1 NumPSLA, a program for enumerating pseudoline arrangements and abstract order types

The purpose of this program is to enumerate abstract order types. (sometimes also called generalized configuration or a pseudoconfiguration)

The program enumerates the objects without repetition and with negligible storage.

We consider nondegenerate cases only: no three points on a line.

We abbreviate *abstract order type* by AOT and *oriented abstract order type* by OAOT. (An *oriented* abstract order type can be distinguished from its mirror image by OAOT.)

1.1 Pseudoline arrangements and abstract order types

We consider everything *oriented*, i.e., the mirror object can be isomorphic or not. Also, only *simple*: No three curves through a point.

A *projective* pseudoline arrangement (PSLA) is a family of centrally symmetric closed Jordan curves on the sphere such that any two curves intersect in two points, and they intersect transversally at these points.

An *affine* PSLA is a family of Jordan curves in the plane that go to infinity at both ends and that intersect pairwise exactly once, and they intersect transversally at these points.

An *x-monotone* PSLA (*wiring diagram*, primitive sorting network) is an affine PSLA with *x*-monotone curves.

We consider two objects as equivalent under deformation by orientation-preserving isotopies of the sphere, or the plane, respectively. (An *x-monotone* PSLA must remain *x-monotone* throughout the deformation.)

A *marked* OAOT is an OAOT with a marked point on the convex hull.

Figure 1: Relations between different concepts. There are different paths from the top left to the bottom right, which apply specialization or geometric reinterpretation in different order.

See Aichholzer and Krasser, Abstract order type extension and new results on the rectilinear crossing number. Comput. Geom. 36 (2007), 2–15, Table 1.

n	[A006247] #AOT	[A063666] #realizable AOT	Δ	relative Δ	#mirror-symmetric AOT	[A006245] # <i>x</i> -monotonePSLA
3	1	1	0	0	1	2
4	2	2	0	0	2	8
5	3	3	0	0	3	62
6	16	16	0	0	12	908
7	135	135	0	0	28	24,698
8	3,315	3,315	0	0	225	1,232,944
9	158,830	158,817	13	0,01 %	825	112,018,190
10	14,320,182	14,309,547	10,635	0,07 %	13,103	18,410,581,880
11	2,343,203,071	2,334,512,907	8,690,164	0,37 %	76,188	5,449,192,389,984
12	691,470,685,682					2,894,710,651,370,536

The last column counts the objects that the program actually enumerates one by one (almost, because we try to apply shortcuts). These numbers are known up to $n = 15$. For example, to get the 158,830 AOTs with 9 points, we go through all 1,232,944 xPSLAs with 8 pseudolines.

$$\#OAOT = 2 \times \#AOT - \#\text{mirror-symmetric AOT} \quad [\text{A006246}]$$

$\#AOT$ equals the number of simple projective pseudoline arrangements with a marked cell.

According to OEIS, three different sequences give “the number of primitive sorting networks on n elements”: A006245, A006246, A006248.

2 The main program

```

3  #define MAXN 11      /* The maximum number of pseudolines for which the program will work. */
    < Include standard libraries 6 >
    < Types and data structures 5 >
    < Global variables 8 >
    < Subroutines 24 >
    < Core subroutine for recursive generation 14 >
    int main(int argc, char *argv[])
    {
        < Parse the command line 9 >;
    #if readdatabase      /* reading from the database */
        < Read all point sets of size  $n_{max} + 1$  from the database and process them 70 >
        return 0;
    #endif
    #if enumAOT
        < Initialize statistics and open reporting file 51 >;
        < Start the generation 15 >;
        < Report statistics 53 >;
    #endif
        return 0;
    }

```

2.1 Preprocessor switches

The program has the enumeration procedure at its core, but it can be configured to perform different tasks, by setting preprocessor switches at compile-time.

We assume that the program will anyway be modified and extended for specific counting or enumeration tasks, and it makes sense to set these options at compile-time.

(Other options, which are less permanent, can be set by command-line switches.)

```

4  #define enumAOT 1      /* purpose is enumeration of AOTs */
    /* Other purposes might be enumeration of PSLAs */
    #define readdatabase 0 /* version for reading point sets of the order-type database */
    #define generatelist 0 /* List all PSLAs plus their IDs, as preparation for generating exclude-files of
        nonrealizable AOTs, requires  $enumAOT \equiv 1$ . */
    #define profile 1     /* gather statistics and profiling information */

```

¶ Type definitions.

```

5  < Types and data structures 5 > ≡
    typedef enum { false, true } boolean;

```

See also chunks 11, 58, and 66*

This code is used in chunk 3*.

¶ Standard libraries

```

6  ⟨Include standard libraries 6⟩ ≡
   #include <stdio.h>
   #include <stdint.h>
   #include <stdlib.h>
   #include <string.h>
   #include <assert.h>

```

See also chunk 68*.

This code is used in chunk 3*.

2.2 Auxiliary macros for for-loops

```

7  #define for_int_from_to(x, first, last) for (int x ← first; x ≤ last; x++)
   format for_int_from_to for
   #define print_array(a, length, begin, separator, end)
       { /* for reporting and debugging */
         printf(begin);
         for_int_from_to (j, 0, length - 1) {
           if (j > 0) printf(separator);
           printf("%d", a[j]);
         }
         printf(end);
       } /* for gcc, compile with -Wno-format-zero-length to suppress warnings */

```

2.3 Command-line arguments

```

8  #define PRINT_INSTRUCTIONS
       printf("Usage: %s %n [-exclude %excludefile] %n [splitlevel %parts %part] %n [fileprefix] \n",
           argv[0]);
⟨Global variables 8⟩ ≡
   small_int n_max, split_level;
   unsigned int parts ← 1000, part ← 0;
   char *fileprefix ← "reportPSLA"; /* default name */
   char *exclude_file_name ← 0;
   char fname[200] ← "";
   FILE *reportfile ← 0;

```

See also chunks 12, 18, 28, 33, 37, 46, 50*, and 64*

This code is used in chunk 3*.

```

9  ¶⟨Parse the command line 9⟩ ≡
   if (argc < 2) n_max ← 7;
   else {
     if (argv[1][0] ≡ '-') { /* first argument "--help" gives help message. */
       PRINT_INSTRUCTIONS;
       exit(0);
     }
     n_max ← atoi(argv[1]);
   }
   printf("Enumeration up to %n = %d pseudolines, %d points. \n", n_max, n_max + 1);
   if (n_max > MAXN) {
     printf("The largest allowed value is %d. Aborting. \n", MAXN);
     exit(1);
   }
   int argshift ← 0;

```

```

if (argc ≥ 3) {
  if (strcmp(argv[2], "-exclude") ≡ 0) {
    if (argc ≥ 4) {
      exclude_file_name ← argv[3];
      argshift ← 2;
      printf("Excluding entries from file %s.\n", exclude_file_name);
      ⟨ Open the exclude-file and read first line 20 ⟩
    }
    else {
      PRINT_INSTRUCTIONS;
      exit(1);
    }
  }
}
if (argc ≥ 3 + argshift) {
  split_level ← atoi(argv[2 + argshift]);
  if (split_level ≡ 0) {
    if (argv[2 + argshift][0] ≠ '-') fileprefix ← argv[2 + argshift];
    snprintf(fname, sizeof(fname) - 1, "%s-%d.txt", fileprefix, n_max);
    parts ← 1;
  }
  else {
    if (argc ≥ 4 + argshift) parts ← atoi(argv[3 + argshift]);
    if (argc ≥ 5 + argshift) part ← atoi(argv[4 + argshift]);
    part ← part % parts;
    if (argc ≥ 6 + argshift) fileprefix ← argv[5 + argshift];
    snprintf(fname, sizeof(fname) - 1, "%s-%d-S%d-part_%d_of_%d.txt", fileprefix, n_max, split_level,
      part, parts);
    printf("Partial enumeration: split at level n = %d. Part %d of %d.\n", split_level, part,
      parts);
  }
  printf("Results will be reported to file %s.\n", fname);
  fflush(stdout);
}

```

This code is used in chunk 3*.

3 Representations of pseudoline arrangements

Here is an x -monotone pseudoline arrangement with $n = 5$ pseudolines, together with a primitive graphic representation as produced by the program *print_wiring_diagram*:

Pseudoline 1 starts topmost and ends bottommost. On the right end, the order of all pseudolines is reversed. There is an imaginary pseudoline 0 of very negative slope that intersects all other pseudolines from top to bottom at the very left and again intersects all pseudolines from bottom to top at the very right.

3.1 The local sequences matrix and its inverse

Here is a representation as a two-dimensional array, indicating for each pseudoline i the sequence P_i of crossings with the other lines.

local sequences matrix

$P_0 = [1, 2, 3, 4, 5]$	$\bar{P}_0 = [-, 0, 1, 2, 3, 4]$	
$P_1 = [0, 4, 5, 3, 2]$	$\bar{P}_1 = [0, -, 4, 3, 1, 2]$	$B_1 = [0, 0, 0, 0, 0]$
$P_2 = [0, 3, 4, 5, 1]$	$\bar{P}_2 = [0, 4, -, 1, 2, 3]$	$B_2 = [0, 0, 0, 0, 1]$
$P_3 = [0, 2, 4, 5, 1]$	$\bar{P}_3 = [0, 4, 1, -, 2, 3]$	$B_3 = [0, 1, 0, 0, 1]$
$P_4 = [0, 2, 3, 1, 5]$	$\bar{P}_4 = [0, 3, 1, 2, -, 4]$	$B_4 = [0, 1, 1, 1, 0]$
$P_5 = [0, 2, 3, 1, 4]$	$\bar{P}_5 = [0, 3, 1, 2, 4, -]$	$B_5 = [0, 1, 1, 1, 1]$

The first row and the first column are determined. Each row has n elements. We also use the data structure for an inverse array \bar{P} , which is essentially the inverse permutation of the rows. The j -th element of \bar{P}_i gives the position in P_i where the crossing with j occurs. The diagonal entries are irrelevant. The column indices in \bar{P} range from 0 to n ; therefore we define the rows to have maximum length $\text{MAXN} + 1$.

```
11 < Types and data structures 5 > +=
    typedef int PSLA [MAXN + 1] [MAXN + 1];
```

3.2 Linked representation

For modifying and extending PSLAs, it is best to work with a linked representation.

Point (j, k) describes the crossing with line k along the line j . $\text{SUCC}(j, k)$ and $\text{PRED}(j, k)$ point to the next and previous crossing on line j . For (k, j) we get the corresponding information for the line k . In the example, we have $\text{SUCC}(2, 3) = 5$ and accordingly $\text{PRED}(2, 5) = 3$.

The infinite rays on line j are represented by the additional line 0: $\text{SUCC}(j, 0)$ is the first (leftmost) crossing on line j , and $\text{PRED}(j, 0)$ is the last crossing. The intersections on line 0 are cyclically ordered $1, \dots, n$. Thus, $\text{SUCC}(0, i) \leftarrow i + 1$ and $\text{SUCC}(0, n) = 1$.

The program works with a single linked-list representation, which is stored in the global arrays *succ* and *pred*. A single pair of these arrays is sufficient for the whole program.

```
12 #define SUCC(i, j) succ[i][j]      /* access macros */
    #define PRED(i, j) pred[i][j]
    #define LINK(j, k1, k2)
        { /* make crossing with k1 and k2 adjacent on line j */
            SUCC(j, k1) ← k2;
            PRED(j, k2) ← k1;
        }
    < Global variables 8 > +=
    int succ[MAXN + 1][MAXN + 1];
    int pred[MAXN + 1][MAXN + 1];
```

4 Recursive Enumeration

We extend an x -monotone pseudoline arrangement of $n - 1$ lines $1, \dots, n - 1$, by threading an additional line n through it from the bottom face to the top face. The new line gets the largest slope of all lines.

Line 0 crosses the other lines in the order $1, 2, \dots, n$.

Figure 2: Threading line n through a face

```

14 ¶(Core subroutine for recursive generation 14) ≡
    void recursive_generate_PSLA_start(int n);
    void recursive_generate_PSLA(int entering_edge, int k_right, int n)
    {
        /* The new line enters a face  $F$  from the bottom. The edge through which it crosses is part of line
           entering_edge, and its endpoint is the crossing with  $k_{\text{right}}$ . */
        int j ← entering_edge;
        int j+ ← k_right;
        while (j+ > j) { /* find right vertex of the current cell  $F$  */
            int jold+ ← j+;
            j+ ← SUCC(j+, j);
            j ← jold+;
        } /* the right vertex is the intersection of  $j$  and  $j^+$  */
        if (j+ ≡ 0) { /*  $F$  is unbounded */
            if (j ≡ n - 1) { /*  $F$  is the top face. */
                LINK(n, entering_edge, 0); /* complete the insertion of line  $n$  */
                <Update counters 17>
                <Indicate Progress 16>;
                <Check for exclusion and set the flag is_excluded 19>
                if (is_excluded) return;
                <Gather statistics about the AOT, collect output 52>
                <Further processing of the AOT 54>
                if (n < n_max)
                    if (n ≠ split.level ∨ countPSLA[n] % parts ≡ part) {
#if enumAOT /* screening one level below */
                        boolean hopeful ← true;
                        if (n ≡ n_max - 1) {
                            <Screen one level below level n_max 45>
                        }
                        if (hopeful)
#endif
                            {
                                localCountPSLA[n + 1] ← 0; /* reset child counter */
                                recursive_generate_PSLA_start(n + 1); /* thread the next pseudoline */
                            }
                        return;
                    }
                else { /* jump to the upper bounding ray of  $F$  */
                    j+ ← j + 1;
                    j ← 0;
                }
            } /* Now the crossing  $j \times j^+$  is the rightmost vertex of the face  $F$ . The edge  $j^+$  is on the upper side.
               If  $F$  is bounded,  $j$  is on the lower side; otherwise,  $j = 0$ . */
            do { /* scan the upper edges of  $F$  from right to left and try them out. */
                k_right ← j;
                j ← j+;
                int k_left ← j+ ← PRED(j, k_right); /*  $j$  is the exiting edge */
                LINK(j, k_left, n); /* insert the crossing to prepare for the recursive call */
                LINK(j, n, k_right);
                LINK(n, entering_edge, j);
                recursive_generate_PSLA(j, k_right, n); /* enter the recursion */
                LINK(j, k_left, k_right); /* undo the changes */
            } while (j+ > j); /* terminate at left endpoint of the face  $F$  or at unbounded ray ( $j^+=0$ ) */
            return;
        }
    }
    void recursive_generate_PSLA_start(int n)
    {

    LINK(1, 2, 0);
    LINK(2, 0, 1);
    LINK(2, 1, 0);
    LINK(0, 1, 2);    /* LINK(0, 2, 3) and LINK(0, 3, 1) will be established shortly in the first recursive call. */
    recursive_generate_PSLA_start(3);

```

This code is used in chunk 3*.

```

16  ¶⟨Indicate Progress 16⟩ ≡
    if (n ≡ n_max ∧ countPSLA[n] % 500000000000 ≡ 0) {    /* 5 × 1010 */
        printf(" .%Ld. .\n", countPSLA[n]);
        PSLA P;
        convert_to_PS_array(&P, n);
        print_pseudolines_short(&P, n);
        fflush(stdout);
    }

```

This code is used in chunk 14.

```

17  ¶⟨Update counters 17⟩ ≡
    countPSLA[n]++;    /* update accession number counter */
    localCountPSLA[n]++;    /* update local counter */

```

This code is used in chunk 14.

5 Handling the exclude-file

The array `excluded_code[3...excluded_length]` contains the decimal code of the next PSLA that should be excluded from the enumeration. During the enumeration, the decimal code of the currently visited tree node (as stored in `localCountPSLA`) agrees with `excluded_code` up to position `matched_length`.

It is assumed that the codes in the exclude-file are sorted in strictly increasing lexicographic order, and no code is a prefix of another code.

To give an example, here are a few lines from the middle of the file `exclude10.txt`:

```

1.3.7.12.9.17.45
1.3.7.12.9.18.35
1.3.7.12.9.18.37
1.3.7.12.9.19
1.3.7.12.9.20
1.3.7.12.9.21.36
1.3.7.12.9.21.37

```

NOTE: As currently implemented, the handling of the exclude-file does not work together with the parallelization through the `splitlevel` option. This is not checked.

```

18  ⟨Global variables 8⟩ +≡
    unsigned excluded_code[MAXN + 3];
    int excluded_length ← 0;
    int matched_length ← 0;    /* These initial values will never lead to any match. */
    FILE *exclude_file;
    char exclude_file_line[100];

```

```

19  ¶⟨Check for exclusion and set the flag is_excluded 19⟩ ≡
    boolean is_excluded ← false;
    if ( $n \equiv \text{matched\_length} + 1 \wedge \text{localCountPSLA}[n] \equiv \text{excluded\_code}[n]$ ) {
        matched_length ← n;      /* one more matching entry was found. */
        if ( $\text{matched\_length} \equiv \text{excluded\_length}$ ) {      /* skip this PS�A and the whole subtree */
            is_excluded ← true;
            ⟨Get the next excluded decimal code from the exclude-file 21⟩
            ⟨Determine the matched length matched_length 22⟩
        }
    }

```

This code is used in chunk 14.

```

20  ¶⟨Open the exclude-file and read first line 20⟩ ≡
    exclude_file ← fopen(exclude_file_name, "r");
    ⟨Get the next excluded decimal code from the exclude-file 21⟩
    matched_length ← 2;

```

This code is used in chunk 9.

¶ I don't know why the following program piece is so badly formatted by **cweave**.

```

21  ⟨Get the next excluded decimal code from the exclude-file 21⟩ ≡
    do { if (fscanf(exclude_file, "%s\n", exclude_file_line) ≠ EOF) { char *str1 ← exclude_file_line;
    char *token, *saveptr;
    excluded_length ← 2;
    while (true) { token ← strtok_r(str1, ".", &saveptr);
    if (token ≡ Λ) break;
    assert ( excluded_length < MAXN + 3 - 1 );
    excluded_code[++excluded_length] ← atoi(token);
    str1 ← Λ; } }
    else {
        excluded_length ← 0;      /* end of file reached. */
        fclose(exclude_file);
    }
    }
    while (excluded_length > n_max) ;      /* patterns longer than n_max are filtered. */

```

This code is used in chunks 19 and 20

¶ (The following program piece could be accelerated if the exclude-file would not store every decimal code completely but indicate only the deviation from the previous code.)

```

22  ⟨Determine the matched length matched_length 22⟩ ≡
    matched_length ← 2;
    while ( $\text{excluded\_code}[\text{matched\_length} + 1] \equiv \text{localCountPSLA}[\text{matched\_length} + 1] \wedge \text{matched\_length} < \text{excluded\_length} \wedge \text{matched\_length} < n$ )
        matched_length++;

```

This code is used in chunk 19.

6 Conversion between different representations

¶ Convert from linked list to array.

Input: PS�A with n lines $1 \dots n$, stored in *succ*. Output: PS�A-Array P of size $(n+1) \times (n-1)$ for pseudoline arrangement on n pseudolines.

```

24  ⟨Subroutines 24⟩ ≡
    void convert_to_PS_array(PSLA *P, int n)
    {
        int j ← 1;

```

```

for_int_from_to (i, 0, n) {
  for_int_from_to (p, 0, n - 1) {
    (*P)[i][p] ← j;
    j ← SUCC(i, j);
  }
  j ← 0;    /* j starts at 0 except for the very first line. */
}

```

¶ The inverse PS�A matrix \bar{P} gives the following information: $\bar{P}_{jk} = p$ if the intersection between line j and line k is the p -th intersection on line j ($p = 0, \dots, n - 1$). This is used to answer orientation queries about the pseudoline arrangement, and about the dual point set, see Section [7](#).

25 \langle Subroutines [24](#) $\rangle + \equiv$

```

void convert_to_inverse_PS_array(PSLA * $\bar{P}$ , int n)
{
  int j ← 1;
  for_int_from_to (i, 0, n) {
    for_int_from_to (p, 0, n - 1) {
      (* $\bar{P}$ )[i][j] ← p;
      j ← SUCC(i, j);
    }
    j ← 0;    /* j starts at 0 except for the very first line. */
  }
}

```

7 The orientation predicate

We compute the orientation predicate in constant time from the inverse permutation array \bar{P} . It is a **boolean** predicate that returns *true* if the points i, j, k are in counterclockwise order. It works only when the three indices are distinct.

It is computed by comparing the intersections on line j .

If $i < j < k$, this predicate is *true* if the intersection of lines i and k lies above line j . When i, j, k are permuted, the predicate must change according to the sign of the permutation. For documentation purposes, we specify an expression *getOrientation_explicit* that distinguishes all $3!$ possibilities in which the indices i, j, k can be ordered. *getOrientation* is a simpler, equivalent, expression.

26 **#define** *getOrientation_explicit*(\bar{P}, i, j, k)
 $(i < j \wedge j < k ? \bar{P}[i][j] > \bar{P}[i][k] : i < k \wedge k < j ? \bar{P}[i][j] > \bar{P}[i][k] : j < i \wedge i < k ? \bar{P}[i][j] < \bar{P}[i][k] :$
 $j < k \wedge k < i ? \bar{P}[i][j] > \bar{P}[i][k] : k < j \wedge j < i ? \bar{P}[i][j] > \bar{P}[i][k] : k < i \wedge i < j ? \bar{P}[i][j] < \bar{P}[i][k] : 0)$
#define *getOrientation*(\bar{P}, i, j, k) $((i < j) \oplus (j < k) \oplus (\bar{P}[j][i] > \bar{P}[j][k]))$

¶ extreme points from the PS�A.

This is easy; we just scan the top face. We know that 0, 1, and n belong to the convex hull. 0 represents the line at ∞ .

The input is taken from the global variable *succ*. (*pred* is not used.)

```

27  ⟨ Subroutines 24 ⟩ +≡
    small_int upper_hull_PSLA(int n, small_int *hulledges)
    {
        hulledges[0] ← 0;
        small_int hullsize ← 1;
        int k ← 0, kleft, kright ← 1;
        do { /* scan the edges of the top face F from left to right */
            kleft ← k;
            k ← kright;
            kright ← SUCC(k, kleft);
            hulledges[hullsize++] ← k;
        } while (kright ≠ 0);
        return hullsize; /* Result is the number of extreme points. */
    }

```

8 Unique identifiers, accession numbers, Dewey decimal notation

The recursive enumeration algorithm imposes an implicit tree structure on PSLAs: the parents of a PSLA with n lines is the unique PSLA on $n - 1$ lines from which it is generated. We number the children of each node in the order in which they are generated, starting from 1. The sequence of labels on the path from the root to a node gives a unique identifier to each node in the tree. (This is, however, specific to details of the enumeration algorithm: in which order edges are considered for crossing in the insertion, the choice of lexicographic criterion.)

The purpose of this scheme is that it allows to identify a PSLA even if we parallelize the computation, and one thread of the program only visits certain branches of the tree.

```

28  ⟨ Global variables 8 ⟩ +≡
    unsigned localCountPSLA[MAXN + 3];

29  ¶ ⟨ Subroutines 24 ⟩ +≡
    void print_id(int n)
    {
        printf("%d", localCountPSLA[3]);
        for_int_from_to (i, 4, n) printf("%.d", localCountPSLA[i]);
    }

```

9 Output

¶ Prettyprinting of a wiring diagram. Fill a buffer of lines columnwise from left to right.

```

            if (i > 1) printf("!");

```

```

    for_int_from_to (j, 1, n - 2) printf("%c", TO_CHAR((*P)[i][j]));
  }
}

```

9.1.1 A more compact fingerprint

Sufficient to know

$B_i[j] = 1$ if $P_i[j] < i$, see Felsner, Chapter 6.

binary arrays B_1, \dots, B_n . The first column is fixed. The first row B_1 and the last row B_n is fixed, and they need not be coded. Also, since row B_i contains $i - 1$ ones, we can omit the last entry per row, since it can be reconstructed from the remaining entries. Thus we encode the $(n - 2) \times (n - 2)$ array obtained removing the borders from the original $n \times n$ array.

We code 6 bits into an ASCII symbol, using the small and capital letters, the digits, and the symbols + and -.

Since we use this encoding for the case when n is known, we need not worry about terminating the code.

(Replace matrices would offer even more savings.)

```

33 #define FINGERPRINT_LENGTH 30      /* enough for  $13 \times 13$  bits plus terminating null */
    <Global variables 8> +=
    char fingerprint[FINGERPRINT_LENGTH];

```

```

34 ¶<Subroutines 24> +=
    char encode_bits(int acc)
    {
        if (acc < 26) return (char)(acc + (int) 'A');
        else if (acc < 52) return (char)(acc - 26 + (int) 'a');
        else if (acc < 62) return (char)(acc - 52 + (int) '0');
        else if (acc ≡ 62) return '+';
        else return '-';
    }

    void compute_fingerprint(PSLA *P, int n)
    {
        int charpos ← 0;
        int bit_num ← 0;
        int acc ← 0;

10 Abstract order types

10.1 Lexmin for PSLA representation

In order to generate every AOT only once, we check whether the representation is smallest among all PSLAs that produce AOTs, that are *equivalent* by rotation and reflection.

Lexicographically smallest. We have to try all “boundary points”(?) as pivot points. The average number of extreme vertices is slightly less than 4. It does not pay off to shorten the loop considerably. (The average *squared* face size matters!)

To determine !!!! whether a PSLA is the lex-smallest among all PSLAs representing an AOT, we scan the PSLA matrix row-wise *from right to left*. In comparison with the more natural left-to-right order, this gives, experimentally, a quicker way to eliminate tentative PSLA than the left-to-right order.

```

37  ⟨ Global variables 8 ⟩ +≡
    int Sequence[MAXN + 1][MAXN + 1];
        /* Sequence[r][p] gives the p-th crossing on the r-th hull edge. */
    int new_label[MAXN + 1][MAXN + 1]; /* When the r-th hull edge is used in the role of line 0,
        new_label[r][j] gives index that is use for the (original) line j. */
    int candidate[2*(MAXN + 1)]; /* list of candidates, gives index r into hulledges */
    int current_crossing[2*(MAXN + 1)]; /* indexed by candidate number */
    int P_1_n_forward[MAXN + 1];
    int P_1_n_reverse[MAXN + 1];

38  ¶(Subroutines 24) +≡
    void prepare_label_arrays(small_int n, small_int *hulledges, small_int hullsize)
    {
        for_int_from_to (r, 0, hullsize - 1)
            if (P_1_n_reverse[r] ≡ P_1_n_forward[0] ∨ (r > 0 ∧ P_1_n_forward[r] ≡ P_1_n_forward[0])) {
                /* otherwise not needed. */
                int line0 ← hulledges[r];
                new_label[r][line0] ← 0;
                int i ← (r < hullsize - 1) ? hulledges[r + 1] : 0; /* 0 ≡ hulledges[0] */
                for_int_from_to (p, 1, n) {
                    new_label[r][i] ← p;
                    Sequence[r][p] ← i;
                    i ← SUCC(line0, i);
                }
            }
    }

```

10.2 Compute the lex-smallest representation

The input is taken from the global *succ* and *pred* arrays. The function assumes that *hulledges* and *hullsize* have been computed.1)

```

39  ⟨ Subroutines 24 ⟩ +≡
    void compute_lex_smallest_PSLA(PSLA *P, small_int n, small_int *hulledges, small_int hullsize)
    {
        for_int_from_to (q, 0, n - 1) (*P)[0][q] ← q + 1; /* row 0 */
        for_int_from_to (r, 0, hullsize - 1) P_1_n_forward[r] ← P_1_n_reverse[r] ← 0;
        /* no screening. dummy values ensure that prepare_label_arrays will prepare all label arrays */
        prepare_label_arrays(n, hulledges, hullsize);
        int numcandidates ← 0;
        for_int_from_to (r, 0, hullsize - 1) candidate[numcandidates++] ← r;
        int numcandidates_forward ← numcandidates;
        for_int_from_to (r, 0, hullsize - 1) candidate[numcandidates++] ← r;
        for_int_from_to (p, 1, n) { /* compute row P_p of the PSLA array P */
            (*P)[p][0] ← 0;
            for_int_from_to (c, 0, numcandidates - 1) {
                int r ← candidate[c];

```

```

    current_crossing[c] ← hulledges[r];    /* plays the role of line 0 */
  }
  for_int_from_to (q, 1, n - 1) {
    /* Compute  $P_{p,n-q}$  by taking the minimum over all candidate choices of line 0. */
    int c;
    int new_candidates, new_candidates_forward;
    int current_min ← n + 1;    /* essentially  $\infty$  */
    boolean reversed ← false;
    int pos ← p;    /* position of line 0; the line we are currently searching in Sequence */
    for (c ← 0; c < numcandidates_forward; c++) {
      ⟨Process candidate  $c$ , keep in list and advance new_candidates if equal; reset new_candidates if
        better value than current_min 40⟩
    }
    new_candidates_forward ← new_candidates;    /* can be reset in the next loop */
    reversed ← true;
    pos ← n + 1 - p;
    for (; c < numcandidates; c++) {
      ⟨Process candidate  $c$ , keep in list and advance new_candidates if equal; reset new_candidates if
        better value than current_min 40⟩
    }
    numcandidates_forward ← new_candidates_forward;
    numcandidates ← new_candidates;
    (*P)[p][n - q] ← current_min;    /* could enter a shortcut as soon as  $\text{numcandidates} \equiv 1$  */
  }
}

```

¶ The list of candidates is scanned and simultaneously overwritten with new values.

```

40 ⟨Process candidate  $c$ , keep in list and advance new_candidates if equal; reset new_candidates if better value
    than current_min 40⟩ ≡
  int r ← candidate[c];
  int i ← Sequence[r][pos];    /* We are proceeding on line  $i$  */
  int j ← current_crossing[c];
  j ← reversed ? SUCC(i, j) : PRED(i, j);
  int a ← new_label[r][j];
  if (reversed ∧ a ≠ 0) a ← n + 1 - a;
  if (a < current_min)    /* new record: */
  {
    new_candidates ← new_candidates_forward ← 0;
    current_min ← a;
  }
  if (a ≡ current_min) {    /* candidate survives. */
    candidate[new_candidates] ← r;
    current_crossing[new_candidates] ← j;
    new_candidates++;
  }    /* Otherwise the candidate is skipped. */

```

This code is used in chunk 39.

¶ The output parameters have only a meaning if the test returns *true*. *has_fixpoint* is only set if the PSLA is mirror-symmetric.

We scan the entries of P row-wise from right to left. We maintain a list of solutions, which are still *candidates* to be lex-smallest. Initially we have $2 \times \text{hullsize}$ candidates, *hullsize* “forward” candidates and the same number of mirror-symmetric, reversed candidates.

Candidates $0 \dots \text{numcandidates_forward} - 1$ are forward candidates. The remaining candidates up to $\text{numcandidates} - 1$ are reverse (mirror) candidates.

If information about mirror symmetry is not necessary, then the mirror candidates can be omitted.

10.3 Streamlined version

Fast screening of candidates

Let i and j be two consecutive edges on the upper envelope. The quantity $Q(i, j)$ is defined as follows, see Figure 3a.

Figure 3: (a) An example with $Q(i, j) = 4$ and $\bar{Q}(i, j) = 5$; (b) an example with $Q(0, 1) = \bar{Q}(0, 1) = 4$

Let $i' = \text{PRED}(i, j)$. Walk on line i to the right (by SUCC) from the intersection between i and j until meeting the intersection with i' . Then $Q(i, j)$ is the number of visited points on i , including the endpoints. This convention ensures that $Q(i, j)$ is the value P_{1n} when line i is chosen to play the role of line 0, (and j will become line 1). In the walk along i , we may cross line 0 and wrap around to the left end.

The quantity $\bar{Q}(i, j)$ is defined with switched roles of i and j and with left and right exchanged, and it gives the value P_{1n} in the mirror situation (the *backward* direction) when line j is chosen to play the role of line 0: Let $j' = \text{SUCC}(i, j)$. Walk on line j to the left (by PRED) until meeting line j' .

We apply this definition to all pairs (i, j) of consecutive edges on the upper envelope, starting with $(0, 1)$ and ending with $(n, 0)$. (The last pair is the only pair with $i > j$.)

The numbers $Q(i, j)$ and $\bar{Q}(i, j)$ are between 2 and n , and $Q(i, j) = 2 \iff \bar{Q}(i, j) = 2$.

For $(i, j) = (0, 1)$, the wedge between lines i and j appears actually at the bottom right of the wiring diagram, see Figure 3b. Here we have $Q(0, 1) = \text{PRED}(1, 0) = P_{1n}$, since this is the original situation where line 0 is where it should be. Similarly, for $(i, j) = (n, 0)$, we have to look at the bottom left corner.

...

Our primary criterion in comparing candidates is P_{1n} which is given by $Q(i, j)$ and $\bar{Q}(i, j)$ for the pairs (i, j) of consecutive edges on the upper envelope. This has to be compared against. $Q(0, 1)$.

¶ Screen candidates by comparing the leading entry P_{1n} ,

Compute the leading entry P_{1n} for all candidates directly, without first computing the *label_arrays*. The *label_arrays* are computed afterwards (if at all), and only those that are still necessary. This saves about 20 % of the runtime for enumerating AOTs. If $P_{1n} = 2$ for line 0, the screening has no effect, but otherwise there is a high chance for finding a smaller value P_{1n} for some of the other candidates.

[Observation. The relative frequency of P_{1n} over all PSLAs is about 26 % for 2 and n , about 11 % for 3 and $n - 1$ and decreases towards the middle values. The symmetry can be explained as follows. An xPSLA is essentially a projective oriented PSLA with a marked angle. Going to an adjacent angle and mirroring the PSLA exchanges a with $n + 2 - a$.]

The following program treats each forward candidate i together with the corresponding mirror candidate j . it uses the condition $Q(i, j) = 2 \iff \bar{Q}(i, j) = 2$ to shortcut the computation. (not sure if it brings any advantage.)

For example there are 18,410,581,880 PSLAs with $n = 10$ lines. Of these, only 5,910,452,118 pass the screening test. Eventually, only 2,343,203,071 PSLA are really lex-min, and this is the number of AOTs that we really want.

```

¶ More effective screening at the previous level.

Rather than generating many PSLAs with n lines and eliminating them by screening, it is better not to generate them at all, or to generate only those that have a change of surviving the screening test.

To do this, we apply a test at the previous level.

When adding a new line n , the quantities $Q(i, j)$ can change in a few ways.

1. We cut off some hull vertices. In particular, $(n - 1, 0)$ will always disappear.
2. We generate two new hull vertices: (i, n) with $1 \leq i \leq n - 1$, and $(n, 0)$.
3. In the definition of $Q(i, j)$, line n could take the role of i' . (or j' in the case of $\bar{Q}(i, j)$).
4. In the definition of $Q(i, j)$, line n could intervene between the intersections with j and i' on line i , thus increasing $Q(i, j)$ by 1. (or a similar situation for $\bar{Q}(i, j)$).

A very rudimentary pre-screening test has been implemented, namely for the comparison between $Q(0, 1)$ and $\bar{Q}(1, 0)$:

If $\bar{Q}(0, 1) < Q(1, 0) - 1$ in the arrangement with $n - 1$ lines, then there is no chance to augment this to a *lex-min* PSLA.

Proof: See Figure 3b. There are two cases. If line n does not intersect the segment between 1×0 and $1 \times \text{PRED}(1, 0)$, then $Q(0, 1) = P_{1n}$ is unchanged. $\bar{Q}(1, 0)$ can increase by at most 1. Thus $\bar{Q}(1, 0)$ will beat $Q(1, 0)$.

If line n intersects line 1 between 1×0 and $1 \times \text{PRED}(1, 0)$, then n becomes the new $i' = \text{PRED}(1, 0) = Q(0, 1) = P_{1n}$, and thus P_{1n} has the maximum possible value, n , and is certainly larger than before. $\bar{Q}(1, 0)$ can still increase by at most 1. Thus $\bar{Q}(1, 0)$ will beat $Q(1, 0)$.

For example, with $n = 9$ lines there are 112,018,190 PSLAs, and they generate as children 18,410,581,880 PSLAs with $n = 10$ lines, as mentioned above. The screening test at level $n = 9$ eliminates 22,023,041 out of the 112,018,190 PSLAs (19.66%) because they are not able to produce a lex-min AOT in the next generation. The remaining 89,995,149 PSLAs produce 15,409,623,219 offspring PSLAs with $n = 10$ lines. as opposed to 18,410,581,880 without this pruning procedure. These remaining PSLAs are subject to the screening as before.

```

45  ¶(Screen one level below level  $n_{max}$  45) ≡
    int  $P_{1n} \leftarrow \text{PRED}(1, 0)$ ;    /* insertion of last line  $n$  can only make this larger. */
    if ( $P_{1n} > 3$ ) {
        int  $a \leftarrow 2$ ;
        int  $i2 \leftarrow P_{1n}$ ;    /*  $\equiv i'$  */
        while ( $i2 \neq 2$ ) {    /* compute  $a$  by running along  $j \equiv 1$  */
             $i2 \leftarrow \text{PRED}(1, i2)$ ;
             $a++$ ;
        }    /* Now  $P_{1n\_reverse} \equiv a$  but insertion of line  $n$  could increase this by 1. */
        if ( $a + 1 < P_{1n}$ )  $hopeful \leftarrow false$ ;
    }
    if ( $hopeful$ )  $cpass++$ ; else  $csaved++$ ;

```

This code is used in chunk 14.

      }
    }
}

```

13 Auxiliary routines and conversion to other formats

¶* Input: PSLA with n lines $1..n$ plus line 0 “at ∞ ”. Output: small λ -matrix B for AOT on $n + 1$ points. Line at ∞ corresponds to point 0 on the convex hull.

```

61  ⟨ Subroutines 24 ⟩ +=
    void convert_to_small_lambda_matrix(small_matrix *B, int n)
    {
      for_int_from_to (i, 0, n) {
        (*B)[i][i] ← 0;
      }
      for_int_from_to (i, 1, n) {
        int level ← i - 1;    /* number of lines above the crossing */
        (*B)[0][i] ← level;
        (*B)[i][0] ← n - 1 - level;
        int j ← SUCC(i, 0);
        while (j ≠ 0) {
          if (i < j) {
            (*B)[i][j] ← level;
            level++;
          }
          else {
            level--;
            (*B)[i][j] ← n - 1 - level;
          }
          j ← SUCC(i, j);
        }
      }
    }
}

```

13.1 Extension: Compute crossing-number for each AOT

By <https://oeis.org/A076523>, a set with $n = 12$ points (the maximum that the program is set up to deal with), has at most 18 halving-lines. According to S. Bereg and M. Haghpanah, New algorithms and bounds for halving pseudolines, Discrete Applied Mathematics 319 (2022) 194–206, <https://doi.org/10.1016/j.dam.2021.05.029>, Table 1 on p. 196, the number of halving lines-with for odd numbers n of points are nearly 70 % higher than for the adjacent even values. With a bound of 50 we should be on the safe side. $n = 11$ point has at most 24 halving-lines

```

62  #define MAX_HALVING_LINES 24
    #define MAX_CROSSINGS (MAXN + 1) * MAXN * (MAXN - 1) * (MAXN - 2) / 24
        /* crossing-number goes up to  $\binom{n}{4}$  for  $n$  points */

```

¶* How to check for a crossing.

This algorithm is like the program for drawing the wiring diagram, except that it does not draw anything. consecutive tracks p and $p + 1$. */

Use the formular from Convex quadrilaterals and k -sets, DOI:10.1090/conm/342/06138

The program computes the number of crossings $num_crossings_on_level[p]$ at each level p except for the crossings with line 0. (From this information, there is actually an easy formula to compute the crossing number of the complete graph K_n when it is drawn on this point set.)

```

63 #define CHECK_CROSSING(p)
    {
        {
            int i ← line_at[p];
            int j ← line_at[p + 1];
            if (i < j ∧ next_crossing[i] > i ∧ next_crossing[j] < j ∧ next_crossing[j] ≠ 0)
                /* Line i wants to cross down and line j wants to cross up. */
                /* (In this case, we must actually have next_crossing[i] ≡ j and next_crossing[j] ≡ i.) */
                crossings[num_crossings++] ← p;
                /* The value p indicates a crossing between tracks p and p + 1. */
        }
    }
}

⟨ Subroutines 24 ⟩ +=
int count_crossings(int n)
{
    int next_crossing[MAXN + 1];
    int line_at[MAXN + 1];
    int num_crossings_on_level[MAXN - 1];
    int crossings[MAXN]; /* stack */
    int num_crossings ← 0; /* Initialize */

    for_int_from_to (i, 1, n) {
        next_crossing[i] ← SUCC(i, 0);
        /* current crossing on each line; The first crossing with line 0 "at ∞" is not considered. */
        line_at[i - 1] ← i; /* which line is on the p-th track, 0 ≤ p < n. tracks are numbered p = 0 ... n - 1
                             from top to bottom. */
    }

    for_int_from_to (p, 0, n - 1) num_crossings_on_level[p] ← 1; /* counting the crossing with line 0 */
    /* maintain a stack crossings of available crossings. p ∈ crossings means that tracks p and p + 1 are
       ready to cross */
    for_int_from_to (p, 0, n - 2) CHECK_CROSSING(p)
    while (num_crossings) { /* Main loop */
        int p ← crossings[--num_crossings];
        num_crossings_on_level[p]++; /* update the data structures to CARRY OUT the crossing */
        int i ← line_at[p];
        int j ← line_at[p + 1];
        next_crossing[i] ← SUCC(i, next_crossing[i]);
        next_crossing[j] ← SUCC(j, next_crossing[j]);
        line_at[p] ← j;
        line_at[p + 1] ← i; /* Look for new crossings: */
        if (p > 0) CHECK_CROSSING(p - 1)
        if (p < n - 1) CHECK_CROSSING(p + 1)
    } /* compute result */

    int crossing_formula ← -(n + 1) * n * (n - 1) / 2;
    for_int_from_to (p, 0, n - 1)
        crossing_formula += num_crossings_on_level[p] * (n - 1 - 2 * p) * (n - 1 - 2 * p);
    /* global variable num_halving_lines is set. */
    if (n % 2) /* n odd, number of points even: */
        num_halving_lines ← num_crossings_on_level[(n - 1) / 2];
    else /* n even, number of points odd: */
        num_halving_lines ← num_crossings_on_level[n / 2] + num_crossings_on_level[n / 2 - 1];
    return crossing_formula / 4;
}

```

14 Reading from the Order-Type Database

For simplicity, we work only with numbers in the 16-bit format. Inputs in 8-bit formats are converted.

```
64  ⟨Global variables 8⟩ +≡
    struct { /* 16-bit unsigned coordinates: */
        uint16_tx, y;
    } points[MAXN + 1];
    struct { /* 8-bit unsigned coordinates: */
        uint8_tx, y;
    } pointsmall[MAXN + 1];
```

14.1 Orientation test for points

The return value of *orientation_test* is positive for counterclockwise orientation of the points i, j, k .

```
65  ⟨Subroutines 24⟩ +≡
    large_int orientation_test(int i, int j, int k)
    {
        large_int a ← points[j].x − (large_int) points[i].x; /* range −65535..65535 */
        large_int b ← points[j].y − (large_int) points[i].y;
        large_int c ← points[k].x − (large_int) points[i].x;
        large_int d ← points[k].y − (large_int) points[i].y;
        return a * d − b * c;
    }
```

¶* Intermediate results can be almost 2^{32} in absolute value, and they have signs. The final value is the signed area of the parallelogram spanned by 3 points. Thus it can also be almost 2^{32} in absolute value. 32 bits are not enough to be safe. We use 64 bits.

```
66  ⟨Types and data structures 5⟩ +≡
    typedef int_least64_t large_int; /* for intermediate calculations */
```

14.2 Turn point set with coordinates into PSLA

We insert the lines one by one into the arrangement. This is similar to the insertion of line n in the recursive enumeration procedure. The difference is that we don't try all possibilities for the edge through which line n exits, but we choose the correct edge the by orientation test. By the zone theorem, the insertion of line n takes $O(n)$ time.

We have n points. The first point (point 0) is on the convex hull and the other points are sorted around this point. We get a PSLA with $n - 1$ pseudolines.

```
67  ⟨Subroutines 24⟩ +≡
    void insert_line(int n);
    void PSLA_from_points(int n)
    {
        LINK(1, 0, 2);
        LINK(1, 2, 0);
        LINK(2, 0, 1);
        LINK(2, 1, 0);
        LINK(0, 1, 2);
        /* LINK(0, 2, 3) and LINK(0, 3, 1) will be established shortly in the first recursive call. */
        for_int_from_to (i, 3, n − 1) insert_line(i);
    }
    void insert_line(int n)
    {
        LINK(0, n − 1, n);
        LINK(0, n, 1);
        int entering_edge ← 0, j ← 0, j+ ← 0;
        int kleft, kright;
```

```

while (1) {
  while ( $j^+ > j$ ) { /* find right vertex of the cell */
    int  $j_{old}^+ \leftarrow j^+$ ;
     $j^+ \leftarrow \text{SUCC}(j^+, j)$ ;
     $j \leftarrow j_{old}^+$ ;
  }
  if ( $j^+ \equiv 0$ ) { /*  $F$  is unbounded */
    if ( $j \equiv n - 1$ ) { /*  $F$  is the top face. */
      LINK( $n$ , entering_edge, 0); /* complete insertion of line  $n$  */
      return;
    }
     $j^+ \leftarrow j + 1$ ; /* jump to the upper ray of  $F$  */
     $j \leftarrow 0$ ;
  } /* Now the crossing  $j \times j^+$  is the rightmost vertex of the face  $F$ .  $j^+$  is on the upper side, and if  $F$ 
    is bounded,  $j$  is on the lower side, */
  do { /* scan the upper edges of  $F$  from right to left and find the correct one to cross. */
     $k_{right} \leftarrow j$ ;
     $j \leftarrow j^+$ ;
     $k_{left} \leftarrow j^+ \leftarrow \text{PRED}(j, k_{right})$ ;
  } while ( $j^+ > j \wedge \text{orientation\_test}(j, k_{left}, n) > 0$ );
  LINK( $j$ ,  $k_{left}$ ,  $n$ ); /* insert crossing with  $n$  on line  $j$  */
  LINK( $j$ ,  $n$ ,  $k_{right}$ );
  LINK( $n$ , entering_edge,  $j$ );
  entering_edge  $\leftarrow j$ ;
   $j^+ \leftarrow k_{right}$ ;
}
}

```

14.3 Do the actual reading

We have to figure out the filenames and the format of the stored numbers. We assume that the order types with up to 10 points are stored in the current directory in with the original file names `otypes10.b16`, `otypes09.b16`, `otypes08.b08`, etc., and the order types with 11 points are stored in a subdirectory `Ordertypes` with names `Ordertypes/ord11.00.b16` ... `Ordertypes/ord11.93.b16`.

```

68 <Include standard libraries 6> +≡
#include <fcntl.h>
#include <unistd.h>

69 ¶(*Subroutines 24) +≡
void swap_all_bytes(int n)
{ /* convert numbers from little-endian to big-endian format. */
  for_int_from_to (i, 0, n - 1) {
    points[i].x  $\leftarrow$  (points[i].x  $\gg$  8) | (points[i].x  $\ll$  8);
    points[i].y  $\leftarrow$  (points[i].y  $\gg$  8) | (points[i].y  $\ll$  8);
    /* Assumes 16 bits. It is important that coordinates are UNSIGNED. */
  }
}

70 ¶(*Read all point sets of size  $n_{max} + 1$  from the database and process them 70) ≡
int n_points  $\leftarrow$  n_max + 1;
int bits  $\leftarrow$  n_points  $\geq$  9 ? 16 : 8;
char inputfile[60];
int record_size  $\leftarrow$  (bits/8) * 2 * n_points;
printf("Reading_order_types_of_d_points\n", n_points);
printf(".\n");
printf("One_record_is_d_bytes_long.\n", record_size);
boolean is_big_endian  $\leftarrow$  ( * ( uint16_t * ) "\0\xff" < #100/ );

```

```

if (bits > 8) {
    if (is_big_endian) printf("This computer is big endian.\n");
    else printf("This computer is little-endian. No byte swaps are necessary.\n");
}
if (n_points < 11) {
    snprintf(inputfile, 60, "otypes%02d.b%02d", n_points, bits);
    read_database_file(inputfile, bits, record_size, n_points, is_big_endian);
}
else
    for_int_from_to (num_db, 0, 93) {
        snprintf(inputfile, 60, "Ordertypes/ord%02d_%02d.b16", n_points, num_db);
        read_database_file(inputfile, bits, record_size, n_points, is_big_endian);
    }
printf("%Ld point sets were read from the file(s).\n", read_count);

```

This code is used in chunk 3*.

¶* Open and read database file and process the input points.

```

71  < Subroutines 24 > +=
    long long unsigned read_count ← 0;
    void read_database_file(char *inputfile, int bits, int record_size, int n_points, boolean is_big_endian)
    {
        printf("Reading from file %s\n", inputfile);
        int databasefile ← open(inputfile, O_RDONLY);
        if (databasefile ≡ -1) {
            printf("File could not be opened.\n");
            exit(1);
        }
        while (1) {
            ssize_t bytes_read;
            if (bits ≡ 16) bytes_read ← read(databasefile, &points, record_size);
            else bytes_read ← read(databasefile, &pointsmall, record_size);
            if (bytes_read ≡ 0) break;
            if (bytes_read ≠ record_size) {
                printf("Incomplete file.\n");
                exit(1);
            }
            read_count++;
            if (bits ≡ 16 ∧ is_big_endian) swap_all_bytes(n_points);
            if (bits ≡ 8)
                for_int_from_to (i, 0, n_points - 1) {
                    points[i].x ← pointsmall[i].x;
                    points[i].y ← pointsmall[i].y;
                }
            int n ← n_points - 1;
            PSLA_from_points(n_points);
            small_int hulledges[MAXN + 1];
            small_int hullsize ← upper_hull_PSLA(n, hulledges);
            PSLA P;
            compute_lex_smallest_PSLA(&P, n, hulledges, hullsize);
            compute_fingerprint(&P, n);
            printf("%s:\n", fingerprint);
        }
        close(databasefile);
    }

```

15 Things to consider

1. The `-exclude` option does not work with the parallelization through *splitlevel*. (This is not currently checked.)
2. Using inverse-PSLA makes *screening* slower! It is only good if combined with screening one level before! Computing *inverse_PSLA* one level before *max_n* costs almost nothing.
3. The *succ* and *pred* arrays could be implemented as one-dimensional arrays. Need to check which is faster.

```
72 #define SUCC_ALTERNATE(i,j) succ[i << 4 | j] /* A shift of 4 is sufficient for MAXN + 1 ≡ 16 */
```

List of Refinements

- ⟨ Check for exclusion and set the flag *is_excluded* 19 ⟩ Used in chunk 14.
- ⟨ Compare orientation tests 55 ⟩ Used in chunk 54.
- ⟨ Core subroutine for recursive generation 14 ⟩ Used in chunk 3*.
- ⟨ Determine the matched length *matched_length* 22 ⟩ Used in chunk 19.
- ⟨ Determine the result parameters, depending on the remaining candidates. 49 ⟩ Used in chunk 47.
- ⟨ Further processing of the AOT 54 ⟩ Used in chunk 14.
- ⟨ Gather statistics about the AOT, collect output 52 ⟩ Used in chunk 14.
- ⟨ Get the next excluded decimal code from the exclude-file 21 ⟩ Used in chunks 19 and 20.
- ⟨ Global variables 8 12 18 28 33 37 46 50 64 ⟩ Used in chunk 3*.
- ⟨ Include standard libraries 6 68 ⟩ Used in chunk 3*.
- ⟨ Indicate Progress 16 ⟩ Used in chunk 14.
- ⟨ Initialize statistics and open reporting file 51 ⟩ Used in chunk 3*.
- ⟨ Open the exclude-file and read first line 20 ⟩ Used in chunk 9.
- ⟨ Parse the command line 9 ⟩ Used in chunk 3*.
- ⟨ Print PSLA-fingerprint 35 ⟩ Used in chunk 54.
- ⟨ Process candidate *c*, keep in list and advance *new_candidates* if equal; reset *new_candidates* if better value than *current_min* 40 ⟩ Used in chunk 39.
- ⟨ Process candidate *c*, keep in list and advance *new_candidates* if successful; return *false* if better value than *target_value* is found 48 ⟩ Used in chunk 47.
- ⟨ Read all point sets of size $n_{max} + 1$ from the database and process them 70 ⟩ Used in chunk 3*.
- ⟨ Report statistics 53 ⟩ Used in chunk 3*.
- ⟨ Screen one level below level *n_max* 45 ⟩ Used in chunk 14.
- ⟨ Start the generation 15 ⟩ Used in chunk 3*.
- ⟨ Subroutines 24 25 27 29 31 32 34 38 39 43 47 59 61 63 65 67 69 71 ⟩ Used in chunk 3*.
- ⟨ Types and data structures 5 11 58 66 ⟩ Used in chunk 3*.
- ⟨ Update counters 17 ⟩ Used in chunk 14.
