## 1 NumPSLA, a program for enumerating pseudoline arrangements and abstract order types

The purpose of this program is to enumerate abstract order types (sometimes also called generalized configurations or pseudoconfigurations) and their duals, the pseudoline arrangements (PSLAs).

The program enumerates the objects without repetition and with negligible storage.

We consider the nondegenerate (*simple*) case only: no three points on a line, and no three curves through a point. We abbreviate *abstract order type* by AOT and *oriented abstract order type* by OAOT. (An *oriented* abstract order type can be distinguished from its mirror image.) As a baseline, we consider everything *oriented*, i.e., the mirror object can be isomorphic or not. In the end, we also check for mirror symmetry, and we can choose to report only one orientation of two mirror types.

#### 1.1 Pseudoline arrangements and abstract order types

A projective pseudoline arrangement (PSLA) is a family of centrally symmetric closed Jordan curves on the sphere such that any two curves intersect in two points, and they intersect transversally at these points.

An affine PSLA is a family of Jordan curves in the plane that go to infinity at both ends and that intersect pairwise exactly once, and they intersect transversally at these points.

An x-monotone PSLA (wiring diagram, primitive sorting network) is an affine PSLA with x-monotone curves

We consider two objects as equivalent under deformation by orientation-preserving isotopies of the sphere, or the plane, respectively. (An x-monotone PSLA must remain x-monotone throughout the deformation.)

A marked OAOT is an OAOT with a marked point on the convex hull.

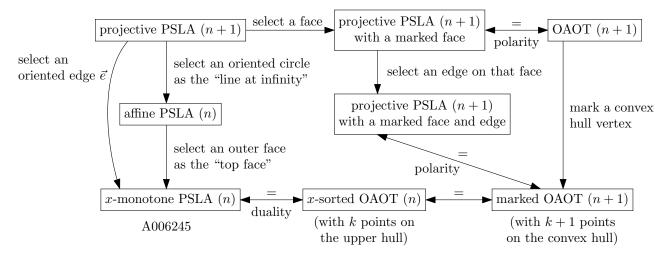

Figure 1: Relations between different concepts. There are different paths from the top left to the bottom right, which apply specialization or geometric reinterpretation in different order.

See Aichholzer and Krasser, Abstract order type extension and new results on the rectilinear crossing number. Comput. Geom. 36 (2007), 2–15, Table 1.

00.	mpat. dcom. oo	(2001), 2 10, 1001	C 1.			
	[A006247]	[A063666]				[A006245]

3	1	1	0	0	1	2
4	2	2	0	0	2	8
5	3	3	0	0	3	62
6	16	16	0	0	12	908
7	135	135	0	0	28	24,698
8	3,315	3,315	0	0	225	1,232,944
9	158,830	158,817	13	$0{,}01\%$	825	112,018,190
10	14,320,182	14,309,547	10,635	$0{,}07\%$	13,103	18,410,581,880
11	2,343,203,071	2,334,512,907	8,690,164	$0,\!37\%$	76,188	5,449,192,389,984
12	691,470,685,682					2,894,710,651,370,536

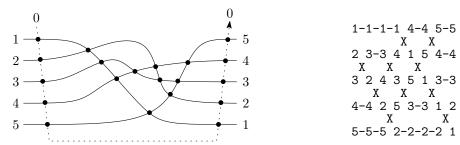

The last column counts the objects that the program actually enumerates one by one (almost, because we try to apply shortcuts). These numbers are known up to n=16. For example, to get the 158,830 AOTs with 9 points, we go through all 1,232,944 xPSLAs with 8 pseudolines, and select a subset by a lexicographic comparison, see Sections 11.2 and 11.4.

$$\#OAOT = 2 \times \#AOT - \#mirror$$
-symmetric AOT [A006246]

#AOT equals the number of simple projective pseudoline arrangements with a marked cell.

## 2 Representations of pseudoline arrangements

Here is an x-monotone pseudoline arrangement with n=5 pseudolines, together with a primitive graphic representation of a different pseudoline arrangement as produced by the function  $print\_wiring\_diagram$  (see Section 10.1):

Pseudoline 1 starts topmost and ends bottommost. On the right end, the order of all pseudolines is reversed. There is an imaginary pseudoline 0 of very negative slope that intersects all other pseudolines from top to bottom at the very left and again intersects all pseudolines from bottom to top at the very right.

#### 2.1 The P-matrix (local sequences matrix) and its inverse

Here is a representation of the right example as a two-dimensional array, indicating for each pseudoline i the sequence  $P_i$  of crossings with the other lines. These sequences are called the *local sequences*. We will refer to the whole matrix as the P-matrix representation of a PSLA.

```
\begin{array}{lll} P_0 = [1,2,3,4,5] & \bar{P}_0 = [-,0,1,2,3,4] \\ P_1 = [0,4,5,3,2] & \bar{P}_1 = [0,-,4,3,1,2] & T_1 = [0,0,0,0,0] \\ P_2 = [0,3,4,5,1] & \bar{P}_2 = [0,4,-,1,2,3] & T_2 = [0,0,0,0,1] \\ P_3 = [0,2,4,5,1] & \bar{P}_3 = [0,4,1,-,2,3] & T_3 = [0,1,0,0,1] \\ P_4 = [0,2,3,1,5] & \bar{P}_4 = [0,3,1,2,-,4] & T_4 = [0,1,1,1,0] \\ P_5 = [0,2,3,1,4] & \bar{P}_5 = [0,3,1,2,4,-] & T_5 = [0,1,1,1,1] \end{array}
```

The first row and the first column are determined. Each row has n elements. We also use the data structure for an inverse array  $\bar{P}$ , which is essentially the inverse permutation of each row. The j-th element of  $\bar{P}_i$  gives the position in  $P_i$  where the crossing with j occurs. The diagonal entries are irrelevant. The column indices in  $\bar{P}$  range from 0 to n; therefore we define the rows to have maximum length MAXN + 1.

The binary matrix T is discussed in Section 10.3. It is defined in terms of the P-matrix by the rule  $T_i[j] = 1$  if  $P_i[j] < i$ .

 $\langle \text{ Types and data structures 4} \rangle \equiv$ 

```
typedef int P_matrix [MAXN + 1][MAXN + 1];
See also chunks 9, 66, and 72
This code is used in chunk 6.
```

#### 2.2 Linked representation

For modifying and extending PSLAs, it is best to work with a linked representation.

Point (j, k) describes the crossing with line k along the line j. SUCC(j, k) and PRED(j, k) point to the next and previous crossing on line j. For (k, j) we get the corresponding information for the line k. In the example, we have SUCC(2, 3) = 5 and accordingly PRED(2, 5) = 3.

The infinite rays on line j are represented by the additional line 0: SUCC(j,0) is the first (leftmost) crossing on line j, and PRED(j,0) is the last crossing. The intersections on line 0 are cyclically ordered  $1, \ldots, n$ . Thus,  $SUCC(0,i) \leftarrow i+1$  and SUCC(0,n)=1.

The program works with a single linked-list representation, which is stored in the global arrays *succ* and *pred*. A single pair of these arrays is sufficient for the whole program.

The main program 3

```
#define SUCC(i,j) succ[i][j] /* access macros */
#define PRED(i,j) pred[i][j]

#define LINK(j,k1,k2)

{ /* make crossing with k_1 and k_2 adjacent on line j */
SUCC(j,k1) \leftarrow k2;
PRED(j,k2) \leftarrow k1;
}

⟨Global variables 5⟩ \equiv
int succ[\texttt{MAXN} + 1][\texttt{MAXN} + 1];
int pred[\texttt{MAXN} + 1][\texttt{MAXN} + 1];
See also chunks 12, 20, 39, 50, 51, and 70
This code is used in chunk 6.
```

## 3 The main program

Each PSLA for n lines has a unique parent with n-1 lines. This defines a tree structure on the PSLAs. The principle of the enumeration algorithm is a depth-first traversal of this tree.

```
/* The maximum number of pseudolines for which the program will work. */
#define MAXN 15
   (Include standard liberies 10)
    Types and data structures 4)
    Global variables 5
   Subroutines 27
   (Core subroutines for recursive generation 15)
  int main(int argc, char *argv[])
  {
     \langle \text{ Parse the command line } 13 \rangle;
#if readdatabase
                         /* reading from the database */
     \langle \text{Read all point sets of size } n_{-}max + 1 \text{ from the database and process them } 76 \rangle
     return 0:
#endif
#if enumAOT
     \langle \text{Initialize statistics and open reporting file 52} \rangle;
     \langle Start the generation 16\rangle;
     \langle \text{ Report statistics 54} \rangle;
#endif
     return 0;
  }
```

#### 3.1 Preprocessor switches

The program has the enumeration procedure at its core, but it can be configured to perfom different tasks, by setting preprocessor switches at compile-time.

We assume that the program will anyway be modified and extended for specific counting or enumeration tasks, and it makes sense to set these options at compile-time.

```
(Other options, which are less permanent, can be set by command-line switches, see Section 3.4.)
```

#### 3.2 On programming style

CWEB provides a good structuring facility while keeping all pieces and the documentation in one place. This leads to a large monolithic program in one file, as opposed to a separation in thematically grouped files that a C-project usually has.

For simplicity, I often use global variables.

Some variations of the program are implemented via preprocessor switches; for others, there is the change-file mechanism of CWEB.

The main program 4

```
\P The boolean type.
\langle \text{Types and data structures 4} \rangle + \equiv
   typedef enum { false, true } boolean;
¶ Standard libraries

          printf("The\_-exclude\_option\_with\_a\_positive\_splitlevel\_%d\_is\_not\_im\
               plemented. \squareAborting. \n", split\_level);
           exit(1);
        if (argc \ge 4 + argshift) parts \leftarrow atoi(argv[3 + argshift]);
        if (argc > 5 + argshift) part \leftarrow atoi(argv[4 + argshift]);
        part \leftarrow part \% parts;
        if (argc \ge 6 + argshift) fileprefix \leftarrow argv[5 + argshift];
        snprintf(fname, sizeof(fname) - 1, "%s-%d-S%d-part_%d_of_%d.txt", fileprefix, n_max, split_level,
        printf("Partial\_enumeration:\_split\_at\_level\_n_= \_%d.\_Part_\_%d.\_of_\_%d.\n", split\_level, part,
             parts);
     printf("Results_{\square}will_{\square}be_{\square}reported_{\square}to_{\square}file_{\square}%s.\n", fname);
     fflush(stdout);
This code is used in chunk 6.
```

#### 4 Recursive Enumeration

We extend an x-monotone pseudoline arrangement of n-1 lines  $1, \ldots, n-1$ , by threading an additional line n through it from the bottom face to the top face. The new line gets the largest slope of all lines. Line 0 crosses the other lines in the order  $1, 2, \ldots, n$ .

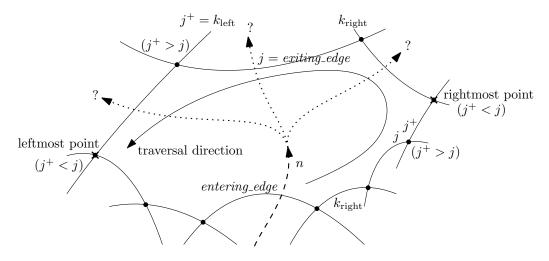

Figure 2: Threading line n through a face

Recursive Enumeration 6

```
void recursive_generate_PSLA(int entering_edge, int k_{right}, int n)
        /* The new line enters a face F from the bottom. The edge through which it crosses is part of line
          entering_edge, and its endpoint is the crossing with k_{\text{right}}. */
    int j \leftarrow entering\_edge;
    int j^+ \leftarrow k_{\text{right}};
     while (j^+ > j) {
                             /* find right vertex of the current cell F *
       int j_{\text{old}}^+ \leftarrow j^+;
       j^+ \leftarrow \text{SUCC}(j^+, j);
       j \leftarrow j_{\text{old}}^+;
        /* the right vertex is the intersection of j and j^+ */
     if (j^+ \equiv 0) {
                      /* F is unbounded */
       if (j \equiv n-1) { /* F is the top face. */
          LINK(n, entering\_edge, 0); /* complete the insertion of line n */
          (Update counters 17)
          \langle \text{Process the PSLA; return if excluded 18} \rangle

     print\_pseudolines\_short(\&P, n);
     fflush(stdout);
```

## 5 Handling the exclude-file

It is assumed that the codes in the exclude-file are sorted in strictly increasing lexicographic order, and no code is a prefix of another code.

To give an example, here are a few lines from the middle of the file exclude10.txt:

```
1.3.7.12.9.17.45
1.3.7.12.9.18.35
1.3.7.12.9.18.37
1.3.7.12.9.19
1.3.7.12.9.20
1.3.7.12.9.21.36
1.3.7.12.9.21.37
```

This code is used in chunk 18.

NOTE: As currently implemented, the handling of the exclude-file does not work together with the parallelization through the *splitlevel* option. This is checked.

The array  $excluded\_code[3...excluded\_length]$  always contains the decimal code of the next PSLA that should be excluded from the enumeration. During the enumeration, the decimal code of the currently visited tree node (as stored in localCountPSLA) agrees with  $excluded\_code$  up to position  $matched\_length$ .

```
\langle \text{Global variables 5} \rangle + \equiv
  unsigned excluded\_code[MAXN + 3];
  int excluded\_length \leftarrow 0;
  int matched\_length \leftarrow 0;
                                    /* These initial values will never lead to any match. */
  FILE *exclude_file;
  char exclude_file_line [100];
¶(Check for exclusion and set the flag is_excluded 21) \equiv
  if (n \equiv matched\_length + 1 \land localCountPSLA[n] \equiv excluded\_code[n]) {
     matched\_length \leftarrow n;
                                 /* one more matching entry was found. */
     if (matched\_length \equiv excluded\_length) {
                                                       /* skip this PSLA and the whole subtree */
        is\_excluded \leftarrow true;
        (Get the next excluded decimal code from the exclude-file 23)
        (Determine the matched length matched_length 24)
   }
See also chunk 57.
This code is used in chunk 18.
¶ (Open the exclude-file and read first line 22) \equiv
   exclude\_file \leftarrow fopen(exclude\_file\_name, "r");
   (Get the next excluded decimal code from the exclude-file 23)
   matched\_length \leftarrow 2;
This code is used in chunk 13.
¶ (Get the next excluded decimal code from the exclude-file 23) \equiv
  do {
     if (fscanf(exclude\_file, "%s\n", exclude\_file\_line) \neq EOF) {
        \mathbf{char} * str1 \leftarrow exclude\_file\_line;
        char *token, *saveptr;
        excluded\_length \leftarrow 2;
        while (true) {
           token \leftarrow strtok\_r(str1, ".", \&saveptr);
          if (token \equiv \Lambda) break;
           assert(excluded\_length < MAXN + 3 - 1);
           excluded\_code[++excluded\_length] \leftarrow atoi(token);
          str1 \leftarrow \Lambda;
        }
     }
     else {
        excluded\_length \leftarrow 0;
                                    /* end of file reached. */
        fclose(exclude\_file);
   } while (excluded\_length > n\_max);
                                                 /* patterns longer than n_{-}max are filtered. */
This code is used in chunks 21 and 22
\P (The following program piece could be accelerated if the exclude-file would not store every decimal code
completely but indicate only the deviation from the previous code.)
\langle Determine the matched length matched_length 24 \rangle \equiv

#### Convert from linked list to P-matrix

Input: PSLA with n lines 1..n, stored in succ. Output: P-matrix of size  $(n+1) \times (n-1)$  for pseudoline arrangement on n pseudolines.

```
\langle \text{Subroutines } 27 \rangle \equiv
   void convert\_to\_P\_matrix(\mathbf{P\_matrix} *P, \mathbf{int} \ n)
      int j \leftarrow 1;
      for_int_from_to (i, 0, n) {
         for_int_from_to (p, 0, n-1) {
            (*P)[i][p] \leftarrow j;
            j \leftarrow \mathtt{SUCC}(i,j);
                        /* j starts at 0 except for the very first line. */
   }
See also chunks 28, 30, 31, 33, 34, 35, 38, 40, 41, 43, 67, 69, 71, 73, 75, and 77
```

This code is used in chunk 6.

#### 6.2 Convert from linked list to inverse P-matrix

The inverse P-matrix matrix  $\bar{P}$  gives the following information:  $\bar{P}_{jk} = p$  if the intersection between line j and line k is the p-th intersection on line j (p = 0, ..., n - 1). This is used to answer orientation queries about the pseudoline arrangement, and about the dual point set, see Section 7.

```
\langle Subroutines 27\rangle + \equiv
  void convert\_to\_inverse\_P\_matrix(\mathbf{P\_matrix} * \bar{P}, \mathbf{int} \ n)
     int j \leftarrow 1;
     for_int_from_to (i, 0, n) {
        for_int_from_to (p, 0, n-1) {
            (*P)[i][j] \leftarrow p;
            j \leftarrow SUCC(i, j);
                       /* j starts at 0 except for the very first line. */
```

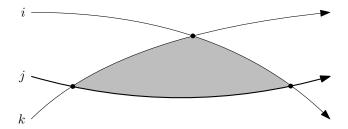

## The orientation predicate

We compute the orientation predicate in constant time from the inverse permutation array  $\bar{P}$ . It is a **boolean** predicate that returns true if the points i, j, k are in counterclockwise order. It works only when the three indices are distinct.

It is computed by comparing the intersections on line j.

If i < j < k, this predicate is true if the intersection of lines i and k lies above line j. When i, j, k are permuted, the predicate must change according to the sign of the permutation. For documentation purposes, we specify an expression  $getOrientation\_explicit$  that distinguishes all 3! possibilities in which the indices i, j, kcan be ordered. getOrientation is a simpler, equivalent, expression.

```
#define getOrientation\_explicit(\bar{P}, i, j, k)
                       \begin{array}{c} (\ddot{i} < j \wedge j < k \;?\; \bar{P}[i][j] > \bar{P}[i][k] : i < k \wedge k < j \;?\; \bar{P}[i][j] > \bar{P}[i][k] : j < i \wedge i < k \;?\; \bar{P}[i][j] < \bar{P}[i][k] : j < k \wedge k < i \;?\; \bar{P}[i][j] > \bar{P}[i][k] : k < j \wedge j < i \;?\; \bar{P}[i][j] > \bar{P}[i][k] : k < i \wedge i < j \;?\; \bar{P}[i][j] < \bar{P}[i][k] : 0 ) \end{array} 
#define getOrientation(\bar{P}, i, j, k) ((i < j) \oplus (j < k) \oplus (\bar{P}[j][i] > \bar{P}[j][k]))
```

## 8 Compute the convex hull points of an AOT from the PSLA

This is easy; we just scan the top face. We know that 0, 1, and n belong to the convex hull. 0 represents the line at  $\infty$ ).

The input is taken from the global variable succ. (pred is not used.) The output is stored in the array hulledges.

```
 \begin{array}{l} \langle \, \text{Subroutines} \, \, 27 \, \rangle \, + \equiv \\ & \quad \text{int} \, \, upper\_hull\_PSLA(\text{int} \, \, n, \text{int} \, *hulledges) \\ \{ \\ & \quad hulledges[0] \leftarrow 0; \\ & \quad \text{int} \, \, hullsize \leftarrow 1; \\ & \quad \text{int} \, \, k \leftarrow 0, \, \, k_{\text{left}}, \, \, k_{\text{right}} \leftarrow 1; \\ & \quad \text{do} \, \, \big\{ \quad / * \, \, \text{scan the edges of the top face} \, F \, \text{from left to right} \, */ \\ & \quad k_{\text{left}} \leftarrow k; \\ & \quad k \leftarrow k_{\text{right}}; \\ & \quad k_{\text{right}} \leftarrow \text{SUCC}(k, k_{\text{left}}); \\ & \quad hulledges[hullsize++] \leftarrow k; \\ \} \, \, \text{while} \, \, (k_{\text{right}} \neq 0); \\ & \quad \text{return} \, \, hullsize; \qquad / * \, \text{Result is the number of extreme points.} \, \, */ \\ \} \end{array}
```

## 9 Unique identifiers, Dewey decimal notation

The recursive enumeration algorithm imposes an implicit tree structure on PSLAs: the parents of a PSLA with n lines is the unique PSLA on n-1 lines from which it is generated. We number the children of each node in the order in which they are generated, starting from 1. The sequence of labels on the path from the root to a node gives a unique identifier to each node in the tree. (This is, however, specific to details of the enumeration algorithm: in which order edges are considered for crossing in the insertion, the choice of lexicographic criterion.)

The purpose of this scheme is that it allows to identify a PSLA even if we parallelize the computation, and one thread of the program only visits certain branches of the tree.

The enumeration tree has only one node on levels 1 and 2. Thus we start the fingerprint at level 3.

(In addition, the PSLAs of each size n are numbered by the global counter countPSLA. This can be used as an "accession number" to identify a PSLA, provided that the PSLAs of size n are enumerated in full.)

```
S1 \( \text{Subroutines 27} \rangle +=
\    unsigned \( localCountPSLA[MAXN + 3]; \quad /* \) another global variable */
\( void \( print_id(int \ n) \) \\
\{ \quad \( printf("%d", localCountPSLA[3]); \\    for_int_from_to \( (i, 4, n) \) \( printf(".%d", localCountPSLA[i]); \\    }
\]
```

## 10 Output

30

#### 10.1 Prettyprinting of a wiring diagram

```
Fill a buffer of lines columnwise from left to right.

#define TO_CHAR(i) ((\mathbf{char})((i < 10 ? (\mathbf{int}) '0' : ((\mathbf{int}) 'A' - 10)) + i))

Subroutines 27 \rangle +\equiv

void print\_wiring\_diagram(\mathbf{int} \ n)

{ /* ASCII, horizontal, column-wise */
```

Output 11

```

assert(n\_crossings * 2 \equiv n * (n-1));
```

}

Output 12

#### 10.2 Fingerprints

A concise description of a PSLA consists of the P-matrix entries, prefixed by the letter P and with the rows separated by ! symbols. The procedure  $print\_pseudolines\_compact$  prints a more compact version that leaves out redundant parts, which are the same in all P-matrices or which can be easily inferred from the reamining information.

#### 10.3 A more compact fingerprint

A PSLA is uniquely determined by the  $n \times n$  binary matrix T, which is defined in terms of the P-matrix by the rule  $T_i[j] = 1$  if  $P_i[j] < i$ . An example is shown in Section 2.1. The fact that this is enough can be seen from the fact that this information is sufficient for drawing the wiring-diagram. It has been shown by Stefan Felsner, On the number of arrangements of pseudolines, Discrete & Computational Geometry 18 (1997), 257–267, doi:10.1007/PL00009318, Theorem 1. See also Felsner, Geometric Graphs and Arrangements, Vieweg, 2004, Chapter 6, Theorem 6.6.

(The so-called *replace matrices* from that paper would offer even more savings.)

The first column of T is fixed. The first row  $T_1$  and the last row  $T_n$  is fixed, and they need not be coded. Also, since row  $T_i$  contains i-1 ones, we can omit the last entry per row, since it can be reconstructed from the remaining entries. Thus we encode the  $(n-2) \times (n-2)$  array obtained removing the borders from the original  $n \times n$  array.

We code 6 bits into on of 64 ASCII symbols, using the 52 small and capital letters, the 10 digits, and the 2 symbols + and -. (Care must be taken when sorting such keys with the UNIX **sort** utility, because, depending on the *locale* settings, the sorting program may conflate uppercase and lowercase letters.)

We use this encoding for the case when n is known. Therefore we need not worry about terminating the code.

```
/* enough for 13 \times 13 bits plus terminating null */
#define FINGERPRINT_LENGTH 30
\langle Subroutines 27\rangle + \equiv
  char fingerprint[FINGERPRINT_LENGTH];
                                                    /* global variable */
  char encode_bits(int acc)
     if (acc < 26) return (char)(acc + (int), A');
     else if (acc < 52) return (char)(acc - 26 + (int) 'a');
     else if (acc < 62) return (char)(acc - 52 + (int), 0);
     else if (acc \equiv 62) return '+';
     else return '-';
  }
  void compute\_fingerprint(\mathbf{P}\_\mathbf{matrix} *P, \mathbf{int} \ n)
     int charpos \leftarrow 0;
     int bit_num \leftarrow 0;
     int acc \leftarrow 0;
```

```
for_int_from_to (i, 1, n-1)
        for_int_from_to (j, 1, n-1) {
           acc \ll = 1;
           if ((*P)[i][j] < i) acc |= 1;
           bit_num += 1;
           if (bit\_num \equiv 6) {
              fingerprint[charpos \leftrightarrow] \leftarrow encode\_bits(acc);
              assert(charpos < FINGERPRINT_LENGTH - 1);
              bit\_num \leftarrow acc \leftarrow 0;
        }
     \textbf{if } \textit{(bit\_num) fingerprint[charpos++]} \leftarrow \textit{encode\_bits(acc} \ll (6-\textit{bit\_num})); \\
     assert(charpos < FINGERPRINT_LENGTH - 1);
     fingerprint[charpos] \leftarrow '\0';

#### 11 Enumerating abstract order types

#### Compute the P-matrix for a different starting edge

For reference we show how to compute the matrix from an arbitrary starting edge. The starting edge is specified by the line  $line\theta$  on which it lies, its right endvertex  $right\_vertex$ , and a a direction. The edge lies between  $left\_vertex \equiv PRED(line0, right\_vertex)$  and  $right\_vertex$  (which fulfills  $right\_vertex \equiv SUCC(line0, left\_vertex)$ ). The direction is in the direction of the succ-pointers if  $reversed \equiv false$  and in the direction of the pred-pointers if  $reversed \equiv true$ . The P-matrix is filled row-wise from right to left.

The main application of this procedure is when we try out different convex hull vertices as pivot points, generating all PSLAs that can represent a given AOT, see Section 11.2. (However, we will never use the procedure compute\_new\_P\_matrix directly, we use a version that computes several such P-matrices in parallel, entry by entry.)

```
\langle Subroutines 27\rangle + \equiv
  void compute_new_P_matrix(P_matrix *P, int n, int line0, int right_vertex, boolean reversed)
     int Sequence[MAXN + 1];
         /* Sequence [p] gives the p-th crossing (in the SUCC-direction) on line start_line. */
    int new\_label[MAXN + 1];
                                    /* new\_label[j] gives the label that is use for the line with the original label
                     /* Sequence and new_label are inverse permutations of each other. */
     new\_label[line\theta] \leftarrow 0;
    int i \leftarrow right\_vertex;
     for_int_from_to (p, 1, n)  {
        new\_label[i] \leftarrow p;
       Sequence[p] \leftarrow i;
       i \leftarrow \texttt{SUCC}(line\theta, i);
     for_int_from_to (q, 0, n-1) (*P)[0][q] \leftarrow q+1; /* row 0 is always the same */
                                      /* compute row P_p of P-matrix */
     for_int_from_to (p, 1, n) {
       int pos \leftarrow reversed ? n + 1 - p : p;
       (*P)[p][0] \leftarrow 0;
       int i \leftarrow Sequence[pos];
       int j \leftarrow line\theta;
           /* We fill row P_p from right to left. The reason for this choice is explained in Section 11.2. */
```

```
\begin{array}{c} \textbf{for\_int\_from\_to} \ (q,1,n-1) \ \{ \ \ /* \ \text{Compute} \ P_{p,n-q} \ */ \\ j \leftarrow reversed \ ? \ \text{SUCC}(i,j) : \ \text{PRED}(i,j); \\ (*P)[p][n-q] \leftarrow new\_label[j]; \\ \} \\ \} \\ \end{array}
```

#### 11.2 Lexicographically smallest P-matrix representation

In order to generate every AOT only once, we check whether the the current P-matrix P the smallest among all P-matrices P' that represent the same AOT, except that the AOT is rotated or reflected.

We have to try all convex hull points as pivot points, and for each pivot point we have to choose two directions (reflected and unreflected). The average number of extreme vertices is slightly less than 4. It does not pay off to shorten the loop considerably. (The average squared face size matters!)

In the lexicographic comparison between PSLAs, we consider the elements of the P-matrix row-wise from right to left, i.e., in the order  $P_{1n}, P_{1,n-1}, \ldots, P_{11}; P_{2n}, P_{2,n-1}, \ldots, P_{21}; \ldots$ , assuming that the entries in each row are numbered from 1 to n (unlike in the C program). In comparison with the more natural left-to-right order, this gives, experimentally, a quicker way to eliminate tentative P-matrices than the left-to-right order.

¶ The label arrays are not computed for those candidates that are excluded by the comparison of the  $P_1 - I_n$ -forward values (unless the flag  $compute_all$  is set).

```
 \begin{array}{l} \langle \operatorname{Subroutines} \ 27 \rangle + \equiv \\ \mathbf{void} \ prepare\_label\_arrays(\mathbf{int} \ n, \mathbf{int} \ *hulledges, \mathbf{int} \ hullsize, \mathbf{boolean} \ compute\_all) \\ \{ & \mathbf{for\_int\_from\_to} \ (r, 0, hullsize - 1) \\ & \mathbf{if} \ (compute\_all \lor P\_1\_n\_reverse[r] \equiv P\_1\_n\_forward[0] \lor (r > 0 \land P\_1\_n\_forward[r] \equiv P\_1\_n\_forward[0])) \\ & \{ & /* \ \text{otherwise not needed.} \ */ \\ & \mathbf{int} \ line0 \leftarrow hulledges[r]; \\ & new\_label[r][line0] \leftarrow 0; \\ & \mathbf{int} \ i \leftarrow (r < hullsize - 1) ? \ hulledges[r + 1] : 0; \\ & /* \ 0 \equiv hulledges[0] \ */ \\ & \mathbf{for\_int\_from\_to} \ (p, 1, n) \ \{ \\ & new\_label[r][i] \leftarrow p; \\ & Sequence[r][p] \leftarrow i; \\ & i \leftarrow \operatorname{SUCC}(line0, i); \\ & \} \\ \} \\ \} \\ \} \end{array}
```

#### 11.3 Compute the lex-smallest representation

The input is taken from the global *succ* and *pred* arrays. The function assumes that *hulledges* and *hullsize* have been computed.

If the test returns *true*, the procedure also sets some output parameters that characterize the symmetry of the AOT: These output parameters — *rotation\_period*, *has\_mirror\_symmetry*, and *has\_fixed\_vertex* — are determined on the way as a side result. *has\_fixed\_vertex* is only set if the PSLA is mirror-symmetric.

We scan the entries of P row-wise from right to left. We maintain a list of solutions, which are still candidates to be lex-smallest. Initially we have  $2 \times hullsize$  candidates, hullsize "forward" candidates and the same number of mirror-symmetric, reversed candidates.

The candidates with numbers  $0 \dots numcandidates\_forward-1$  are forward candidates. The remaining candidates up to numcandidates-1 are reverse (mirror) candidates.

If information about mirror symmetry is not necessary, then the mirror candidates can be omitted.

```
\langle Subroutines 27\rangle + \equiv
  void compute\_lex\_smallest\_P\_matrix(\mathbf{P}\_matrix *P, int n, int *hulledges, int hullsize)
     for_int_from_to (q, 0, n - 1) (*P)[0][q] \leftarrow q + 1;
                                                                  /* row 0 */
     prepare\_label\_arrays(n, hulledges, hullsize, true);
     int numcandidates \leftarrow 0;
     for_int_from_to (r, 0, hull size - 1) candidate [numcandidates \leftrightarrow] \leftarrow r;
     int numcandidates\_forward \leftarrow numcandidates;
     for_int_from_to (r, 0, hull size - 1) candidate [num candidates ++] \leftarrow r;
     for_int_from_to (p, 1, n) { /* compute row P_p of the P-matrix */
        (*P)[p][0] \leftarrow 0;
       for_int_from_to (c, 0, numcandidates - 1) {
          int r \leftarrow candidate[c];
          current\_crossing[c] \leftarrow hulledges[r]; /* plays the role of line 0 */
       for_int_from_to (q, 1, n-1) {
              /* Compute P_{p,n-q} by taking the minimum over all candidate choices of line 0. */
          int c:
          int new_candidates, new_candidates_forward;
          int current\_min \leftarrow n+1;
                                            /* essentially \infty */
          boolean reversed \leftarrow false;
          int pos \leftarrow p;
                              /* position of line 0; the line we are currently searching in Sequence */
          for (c \leftarrow 0; c < numcandidates\_forward; c++) {\langle Process candidate c, keep in list and advance}
               new\_candidates if equal; reset new\_candidates if better value than current\_min is found 42}
          new\_candidates\_forward \leftarrow new\_candidates; /* can be reset in the next loop */
          reversed \leftarrow true;
          pos \leftarrow n + 1 - p;
          for (; c < numcandidates; c \leftrightarrow) {
             Process candidate c, keep in list and advance new_candidates if equal; reset new_candidates if
                  better value than current_min is found 42
          numcandidates\_forward \leftarrow new\_candidates\_forward;
          numcandidates \leftarrow new\_candidates;
                                                 /* could enter a shortcut as soon as numcandidates \equiv 1 */
          (*P)[p][n-q] \leftarrow current\_min;
     }
   }
The list candidate of candidates is scanned and simultaneously overwritten with new values.
\langle Process candidate c, keep in list and advance new-candidates if equal; reset new-candidates if better value
       than current_min is found 42 \rangle \equiv
  int r \leftarrow candidate[c];
                                    /* We are proceeding on line i */
  int i \leftarrow Sequence[r][pos];
  int j \leftarrow current\_crossing[c];
  j \leftarrow reversed ? SUCC(i, j) : PRED(i, j);
  int a \leftarrow new\_label[r][j];
  if (reversed \land a \neq 0) a \leftarrow n+1-a;
  if (a < current_min) /* new record: */
     new\_candidates \leftarrow new\_candidates\_forward \leftarrow 0;
     current\_min \leftarrow a;
  if (a \equiv current\_min) { /* candidate survives. */
     candidate[new\_candidates] \leftarrow r;
     current\_crossing[new\_candidates] \leftarrow j;
     new\_candidates ++;
         /* Otherwise the candidate is skipped. */
This code is used in chunk 41.
```

#### 11.4 Test if the current PSLA gives the lex-smallest P-matrix corresponding to the same AOT

This is a variation of the procedure *compute\_lex\_smallest\_P\_matrix*. The output parameters *rotation\_period*, *has\_mirror\_symmetry*, *has\_fixed\_vertex*, which characterize the symmetry of the AOT, are determined on the way, as a side result.

As a speed-up, there is a fast screening procedure that tries to eliminate a few candidates in advance.

```
\langle \text{Subroutines } 27 \rangle + \equiv
   (Screening procedures 47)
  boolean is_lex_smallest_P_matrix(int n, int *hulledges, int hullsize, int *rotation_period, boolean
            *has_mirror_symmetry, boolean *has_fixed_vertex)
     if (\neg screen(n, hulledges, hullsize)) return false;
#if profile
     numTests ++;
#endif
     prepare\_label\_arrays(n, hulledges, hullsize, false);
     int numcandidates \leftarrow 0;
     for_int_from_to (r, 1, hullsize - 1)
       if (P_1_n_{forward}[r] \equiv P_1_n_{forward}[0]) candidate [numcandidates ++] \leftarrow r;
     int numcandidates\_forward \leftarrow numcandidates;
     for_int_from_to (r, 0, hullsize - 1)

## 12 Screening of candidates to reduce the running time

This code is used in chunk 43.

Suppose we don't have correct labels, but we only known line 0 and line 1. We can still determine the upper right corner  $P_{1n}$  of the P-matrix, as follows (see Figure 3b).

We find  $i' \leftarrow PRED(0,1)$ ; This is line n. The PRED(i',0) would represent the last intersection on line n, which is the value of  $P_{1n}$  that we want, except that we don't have the correct label. We can recover this label by walking along line 0, using the SUCC labels, until we hit line i'.

Let i and j be two consecutive edges on the upper envelope. The quantity Q(i, j) is defined as follows, see Figure 3a.

Let i' = PRED(i, j). Walk on line i to the right (by SUCC) from the intersection between i and j until meeting the intersection with i'. Then Q(i, j) is the number of visited points on i, including the endpoints. This convention ensures that Q(i, j) is the value  $P_{1n}$  when line i is chosen to play the role of line 0, (and j will become line 1). In the walk along i, we may cross line 0 and wrap around to the left end.

The quantity Q(i, j) is defined with switched roles of i and j and with left and right exchanged, and it gives the value  $P_{1n}$  in the mirror situation (the *backward* direction) when line j is chosen to play the role of line 0: Let j' = SUCC(i, j). Walk on line j to the left (by PRED) until meeting line j'.

We apply this definition two all pairs (i, j) of consecutive edges on the upper envelope, starting with (0, 1) and ending with (n, 0). (The last pair is the only pair with i > j.)

The numbers Q(i,j) and  $\bar{Q}(i,j)$  are between 2 and n, and  $Q(i,j)=2 \iff \bar{Q}(i,j)=2$ .

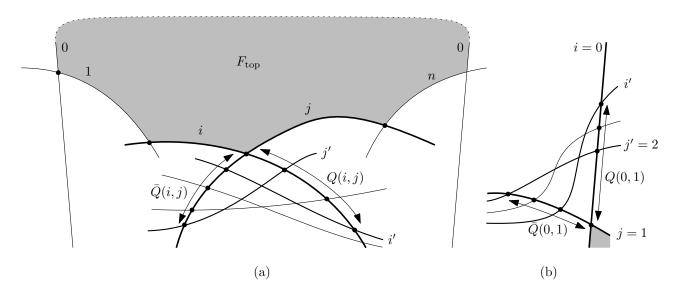

Figure 3: (a) An example with Q(i,j)=4 and  $\bar{Q}(i,j)=5$ ; (b) an example with  $Q(0,1)=\bar{Q}(0,1)=4$ 

For (i,j)=(0,1), the wedge between lines i and j appears actually at the bottom right of the wiring diagram, see Figure 3b. Here we have  $Q(0,1)=\text{PRED}(1,0)=P_{1n}$ , since this is the original situation where line 0 is where it should be. Similarly, for (i,j)=(n,0), we have to look at the bottom left corner.

Our primary criterion in comparing candidates is  $P_{1n}$  which is given by Q(i,j) and  $\bar{Q}(i,j)$  for the pairs (i,j) of consecutive edges on the upper envelope. This has to be compared against. Q(0,1).

#### ¶ Screen candidates by comparing the leading entry $P_{1n}$ ,

Compute the leading entry  $P_{1n}$  for all candidates directly, without first computing the  $label\_arrays$ . The  $label\_arrays$  are computed afterwards (if at all), and only those that are still necessary. This saves about 20% of the runtime for enumerating AOTs. If  $P_{1n}=2$  for line 0, the screening has no effect, but otherwise there is a high chance for finding a smaller value  $P_{1n}$  for some of the other candidates.

[ Observation. The relative frequence of  $P_{1n}$  over all PSLAs is about 26% for 2 and n, about 11% for 3 and n-1 and decreases towards the middle values. The symmetry can be explained as follows. An xPSLA is essentially a projective oriented PSLA with a marked angle. Going to an adjacent angle and mirroring the PSLA exchanges a with n+2-a.

The following program treats each forward candidate i together with the corresponding mirror candidate j. it uses the condition  $Q(i,j)=2\iff \bar{Q}(i,j)=2$  to shortcut the computation. (not sure if it brings any advantage.)

For example there are 18,410,581,880 PSLAs with n=10 lines. Of these, only 5,910,452,118 pass the screening test. Eventually, only 2,343,203,071 PSLA are really lex-min, and this is the number of AOTs that we really want.

```
\langle Screening procedures 47 \rangle \equiv
  boolean screen(int n, int *hulledges, int hullsize)
     P_1_n forward[0] \leftarrow PRED(1,0);
                                            /* because hulledges[1] \equiv 1 */
     for_int_from_to (r, 1, hullsize - 1) {
       int r_next \leftarrow (r+1) \% hullsize;
       int i \leftarrow hulledges[r];
                                           /* i or j plays the role of line 0 */
       int j \leftarrow hulledges[r\_next];
       int i' \leftarrow PRED(j, i);
       int a \leftarrow 2; int j2 \leftarrow SUCC(i, j);
                                  /* compute a by running along i */
       while (j2 \neq i') {
          j2 \leftarrow \texttt{SUCC}(i, j2);
          if (a > P_1_n_forward[0]) break;
                                                    /* shortcut */
       if (a < P_1_n_forward[0]) return false;
        P_{-1}-n-forward [r] \leftarrow a; /* This may not be the precise value if a > P_{-1}-n-forward [0] */
```

```
for_int_from_to (r, 0, hullsize - 1) {
  int r_next \leftarrow (r+1) \% hullsize;
  if (P_1_n_{forward}[r] \equiv 2) {
      P_1_n_reverse[r_next] \leftarrow 2;
          /* The wedge between i and i is a triangle; Q(i,j) and \bar{Q}(i,j) are both 2. */
     continue;
  int i \leftarrow hulledges[r];
  int j \leftarrow hulledges[r\_next];
                                       /* i or j plays the role of line 0 */
  int j' \leftarrow SUCC(i, j);
  int a \leftarrow 2; int i2 \leftarrow PRED(j, i);
              /* compute a by running along j */
     i\mathcal{2} \leftarrow \mathtt{PRED}(j, i\mathcal{2});
     a++;
     if (a > P_1_n_forward[0]) break;
   } while (i2 \neq j');
  if (a < P_1_n_forward[0]) return false;
   P_1_n_reverse[r_next] \leftarrow a;
return true;
```

This code is used in chunk 43.

#### 12.1 More aggressive screening at the previous level

Rather than generating many PSLAs with n lines and eliminating them by screening, it is better not to generate them at all, or to generate only those that have a change of surviving the screening test.

To do this, we apply a test at the previous level.

When adding a new line n, the quantities Q(i,j) can change in a few ways.

- 1. We cut off some hull vertices. In particular, (n-1,0) will always disappear.
- 2. We generate two new hull vertices: (i, n) with  $1 \le i \le n 1$ , and (n, 0).
- 3. In the definition of Q(i,j), line n could take the role of i'. (or j' in the case of  $\bar{Q}(i,j)$ ).
- 4. In the definition of Q(i,j), line n could intervene between the intersections with j and i' on line i, thus increasing Q(i,j) by 1. (or a similar situation for  $\bar{Q}(i,j)$ ).

A very rudimentary pre-screening test has been implemented, namely for the comparison between Q(0,1) and  $\bar{Q}(1,0)$ :

If  $\bar{Q}(0,1) < Q(1,0) - 1$  in the arrangement with n-1 lines, then there is no chance to augment this to a lex-min PSLA.

Proof: See Figure 3b. There are two cases. If line n does not intersect the segment between  $1 \times 0$  and  $1 \times PRED(1,0)$ , then  $Q(0,1) = P_{1n}$  is unchanged.  $\bar{Q}(1,0)$  can increase by at most 1. Thus  $\bar{Q}(1,0)$  will beat Q(1,0).

If line n intersects line 1 between  $1 \times 0$  and  $1 \times PRED(1,0)$ , then n becomes the new  $i' = PRED(1,0) = Q(0,1) = P_{1n}$ , and thus  $P_{1n}$  has the maximum possible value, n, and is certainly larger than before.  $\bar{Q}(1,0)$  can still increase by at most 1. Thus  $\bar{Q}(1,0)$  will beat Q(1,0).

For example, with n=9 lines there are 112,018,190 PSLAs, and they generate as children 18,410,581,880 PSLAs with n=10 lines, as mentioned above. The screening test at level n=9 eliminates 22,023,041 out of the 112,018,190 PSLAs (19.66%) because they are not able to produce a lex-min AOT in the next generation. The remaining 89,995,149 PSLAs produce 15,409,623,219 offspring PSLAs with n=10 lines. as opposed to 18,410,581,880 without this pruning procedure. These remaining PSLAs are subject to the screening as before.

```
¶⟨Screen one level below level n\_max 49⟩ ≡ int P\_1\_n \leftarrow PRED(1,0); /* insertion of last line n can only make this larger. */
```

Statistics 20

 $\P$  We maintain statistics about the effectiveness of this test:

```
\langle \text{Global variables 5} \rangle + \equiv  long long unsigned cpass, csaved;
```

#### 13 Statistics

Characteristics:

- $\bullet$  number h of hull points.
- period p of rotational symmetry on the hull. (The order of the rotation group is h/p.)
- mirror symmetry, with or without fixed vertex on the hull (3 possibilities).

PSLAcount counts OAOT of point sets with a marked point on the convex hull, but no specified traversal direction. http://oeis.org/A006245 (see below) is the same sequence with n shifted by 0. xPSLAcount counts OAOT of point sets with a marked point on the ...?

## 14 Special problem-specific extensions

```
Program extensions for special purposes can be added here: The following data are available:
```

 $lex\_smallest$  ...

The AOT has n+1 points; its convex hull has *hullsize* vertices and is stored in the array *hulledges*. ....  $lex\_smallest$ 

in the *succ* and *pred* arrays

P-matrix is / is not available.

#### 14.1 Further exlusion criteria

If some PSLAs or AOTs and their subtrees should not be considered, they can be filtered here, by setting  $is\_excluded$  to false.

57 (Check for exclusion and set the flag is\_excluded 21)  $+\equiv$  /\* Currently no further exclusion tests. \*/

#### 14.2 Further processing of AOTs

Problem-specific processing can be added here.

```
\langle Further processing of the AOT 58\rangle \equiv /* Currently no further processing of the AOT. */ See also chunks 59, 60, 63, and 64
This code is used in chunk 18.
```

#### 14.2.1 Listing all PSLAs

List all PSLAs plus their IDs, as preparation for generating exclude-files of nonrealizable AOTs.

```
\langle \text{Further processing of the AOT 58} \rangle +\equiv \\ \# \text{if } generate list \\ \text{if } (n \equiv n\_max \land lex\_smallest) \{ \\ \langle \text{Print PSLA-fingerprint 36} \rangle \\ print\_id(n); \\ printf("\n"); \\ \} \\ \# \text{endif}
```

**boolean**  $show \leftarrow true;$ 

#### 14.2.2 Checking correctness of the orientation test

After computing the inverse P-matrix, one can perform a few tests on the order type, using orientation queries. The following test program compares the orientation queries against an explicitly computed three-dimensional  $\Lambda$ -matrix (see Section 15.2).

```
\langle Further processing of the AOT 58\rangle + \equiv
#if 0
   \mathbf{P}_{-}\mathbf{matrix}\ \bar{P};
                        /* the orientation test is computed from this array. */
   convert\_to\_inverse\_P\_matrix(\&\bar{P}, n);
   small\_lambda\_matrixS;
   convert\_to\_small\_lambda\_matrix(\&S, n\_points);
   large\_Lambda\_matrix L;
   convert\_small\_to\_large(\&S,\&L,n\_points);

```

#### 15.2 ("Large") Λ-matrices

69

The three-dimensional  $\Lambda\text{-matrix}$  stores the orientation of all triples.

In this program, entries  $\Lambda_{ijk}$  are only ever accessed for i < j < k. It would be possible to save space by a more elaborate indexing function into a one-dimensional array. More general access could then be provided by a macro  $get\_entry\_large$ .

Natural labeling around the pivot point, which is assumed to lie on the convex hull.

¶ Generating the  $\Lambda$ -matrix. Only for testing purposes. Assumes natural ordering. Assumes general position. Works by plucking points from the convex hull one by one. The input is a  $\lambda$ -matrix A. The result is stored in B.

```
\langle Subroutines 27\rangle + \equiv
  void copy\_small(small\_lambda\_matrix *A, small\_lambda\_matrix *B, int n)
     for_int_from_to (i, 0, n-1)
       for_int_from_to (j, 0, n-1) entry\_small(*B, i, j) \leftarrow entry\_small(*A, i, j);
  void convert\_small\_to\_large (small\_lambda\_matrix *A, large_Lambda_matrix *B, int n)
    small_lambda_matrix Temp;
     copy\_small(A, \& Temp, n);
                                      /* the small matrix Temp will be destroyed */
     for_int_from_to (k, 0, n-1)
       for_int_from_to (i, k+1, n-1)
                                                /* k < i < j */
          for_int_from_to (j, i+1, n-1)
            boolean plus \leftarrow entry\_small(Temp, i, k) < entry\_small(Temp, j, k);
            if (plus) entry\_small(Temp, i, j) ---;
            else entry\_small(Temp, j, i)—;
            (*B)[k][i][j] \leftarrow (*B)[i][j][k] \leftarrow (*B)[j][k][i] \leftarrow plus;
            (*B)[k][j][i] \leftarrow (*B)[i][k][j] \leftarrow (*B)[j][i][k] \leftarrow \neg plus;
          }
  }
```

## 16 Reading from the Order-Type Database

For simplicity, we work only with numbers in the 16-bit format. Inputs in 8-bit formats are converted.

```
70 \langle Global variables 5\rangle +\equiv

struct { /* 16-bit unsigned coordinates: */

uint16_tx, y;
} points[MAXN + 1];

struct { /* 8-bit unsigned coordinates: */

uint8_tx, y;
} pointsmall[MAXN + 1];
```

#### 16.1 Orientation test for points

The return value of orientation\_test is positive for counterclockwise orientation of the points i, j, k.

```
 \begin{array}{ll} \langle \operatorname{Subroutines} \ 27 \rangle + \equiv & \operatorname{large\_int} \ orientation\_test(\operatorname{int} \ i, \operatorname{int} \ j, \operatorname{int} \ k) \\ \{ & \operatorname{large\_int} \ a \leftarrow points[j].x - (\operatorname{large\_int}) \ points[i].x; \\ & \operatorname{large\_int} \ b \leftarrow points[j].y - (\operatorname{large\_int}) \ points[i].y; \\ & \operatorname{large\_int} \ c \leftarrow points[k].x - (\operatorname{large\_int}) \ points[i].x; \\ & \operatorname{large\_int} \ d \leftarrow points[k].y - (\operatorname{large\_int}) \ points[i].y; \\ & \operatorname{return} \ a * d - b * c; \\ \} \end{array}
```

¶ Intermediate results can be almost  $2^{32}$  in absolute value, and they have signs. The final value is the signed area of the parallelogram spanned by 3 points. Thus it can also be almost  $2^{32}$  in absolute value. 32 bits are not enough to be safe. We use 64 bits.

```
72 ⟨Types and data structures 4⟩ +≡

typedef int_least64_t large_int; /* for intermediate calculations */
```

#### 16.2 Turn point set with coordinates into PSLA

We insert the lines one by one into the arrangement. This is similar to the insertion of line n in the recursive enumeration procedure. The difference is that we don't try all possibilities for the edge through which line n exits, but we choose the correct edge the by orientation test. By the zone theorem, the insertion of line n takes O(n) time.

We have n points. The first point (point 0) is on the convex hull and the other points are sorted around this point. We get a PSLA with n-1 pseudolines.

```
\langle \text{Subroutines } 27 \rangle + \equiv
   void insert_line(int n);
   void PSLA\_from\_points(\mathbf{int}\ n)
      LINK(1, 0, 2);
      LINK(1, 2, 0);
      \mathtt{LINK}(2,\ 0,1);
      LINK(2, 1, 0);
      LINK(0, 1, 2);
           /* LINK(0, 2,3) and LINK(0, 3,1) will be established shortly in the first recursive call. */
      for_int_from_to (i, 3, n-1) insert_line(i);
   void insert\_line(int \ n)
      LINK(0, n-1, n);
      LINK(0, n, 1);
      int entering_edge \leftarrow 0, j \leftarrow 0, j^+ \leftarrow 0;
      int k_{\text{left}}, k_{\text{right}};
      while (1) {
         while (j^+>j) { int j_{\text{old}}^+ \leftarrow j^+;
                                     /* find right vertex of the cell */
            \begin{aligned} j^+ &\leftarrow \texttt{SUCC}(j^+, j); \\ j &\leftarrow j_{\text{old}}^+; \end{aligned}
         if (j^+ \equiv 0) { /* F is unbounded */
if (j \equiv n-1) { /* F is the top face. */
                LINK(n, entering\_edge, 0); /* complete insertion of line n */
            j^+ \leftarrow j + 1; /* jump to the upper ray of F */
```

```
} /* Now the crossing j \times j^+ is the rightmost vertex of the face F. j^+ is on the upper side, and if F is bounded, j is on the lower side, */

do { /* scan the upper edges of F from right to left and find the correct one to cross. */

k_{\text{right}} \leftarrow j;

j \leftarrow j^+;

k_{\text{left}} \leftarrow j^+ \leftarrow \text{PRED}(j, k_{\text{right}});
} while (j^+ > j \land orientation\_test(j, k_{\text{left}}, n) > 0);

LINK(j, k_{\text{left}}, n); /* insert crossing with n on line j */

LINK(j, n, k_{\text{right}});

LINK(n, entering\_edge, j);

entering\_edge \leftarrow j;

j^+ \leftarrow k_{\text{right}};
}
```

#### 16.3 Select the order-type files to be read

We have to figure out the filenames and the format of the stored numbers. We assume that the order types with up to 10 points are stored in the current directory in with the original file names otypes10.b16, otypes08.b08, etc., and the order types with 11 points are stored in a subdirectory Ordertypes with names Ordertypes/ord11\_00.b16...Ordertypes/ord11\_93.b16.

```
\langle Include standard liberies 10\rangle + \equiv
 #include <fcntl.h>
#include <unistd.h>
\P\langle \text{Subroutines } 27 \rangle + \equiv
   void swap\_all\_bytes(\mathbf{int} \ n)
          /* convert numbers from little-endian to big-endian format. */
      for_int_from_to (i, 0, n-1) {
        points[i].x \leftarrow (points[i].x \gg 8) \mid (points[i].x \ll 8);
        points[i].y \leftarrow (points[i].y \gg 8) \mid (points[i].y \ll 8);
             /* Assumes 16 bits. It is important that coordinates are unsigned. */
     }
   }
\P(\text{Read all point sets of size } n_max + 1 \text{ from the database and process them } 76) \equiv
   int n\_points \leftarrow n\_max + 1;
   int bits \leftarrow n\_points \geq 9 ? 16 : 8;
   char inputfile [60];
   int record\_size \leftarrow (bits/8) * 2 * n\_points;
   printf("Reading_lorder_ltypes_lof_l%d_lpoints\n", n_points);
   printf(".\n");
   printf("One\_record\_is\_%d\_bytes\_long.\n", record\_size);
   boolean is\_big\_endian \leftarrow (*(uint16\_t*)"\0\xff" < #100);
   if (bits > 8) {
     \mathbf{if}\ (\mathit{is\_big\_endian})\ \mathit{printf}(\texttt{"This\_computer\_is\_big-endian.} \verb|\n"|);\\
     else printf("Thisucomputeruisulittle-endian.uNoubyteuswapsuareunecessary.\n");
   if (n\_points < 11) {
      snprintf(inputfile, 60, "otypes%02d.b%02d", n_points, bits);
      read\_database\_file(inputfile, bits, record\_size, n\_points, is\_big\_endian);
   }
   else
      for_int_from_to (num_db, 0, 93)  {
         snprintf(inputfile, 60, "Ordertypes/ord%02d_%02d.b16", n_points, num_db);
        read_database_file(inputfile, bits, record_size, n_points, is_big_endian);
   printf("%Ld_{\square}point_{\square}sets_{\square}were_{\square}read_{\square}from_{\square}the_{\square}file(s).\n", read_count);
This code is used in chunk 6.
```

Things to consider 28

#### 16.4 Do the actual reading

77

Open and read database file and process the input points.

```
\langle Subroutines 27\rangle + \equiv
  long long unsigned read_count \leftarrow 0;
  void read\_database\_file(char *inputfile, int bits, int record\_size, int n\_points, boolean is\_big\_endian)
     printf("Reading_from_file_%s\n", inputfile);
     int databasefile \leftarrow open(inputfile, O_RDONLY);
     if (databasefile \equiv -1) {
        printf("File\_could\_not\_be\_opened.\n");
        exit(1);
     while (1) {
        ssize_t bytes_read;
        if (bits \equiv 16) by tes\_read \leftarrow read(database file, \& points, record\_size);
        else bytes_read \leftarrow read(databasefile, &pointsmall, record_size);
        if (bytes\_read \equiv 0) break;
        if (bytes\_read \neq record\_size) {
          printf("Incomplete_lfile.\n");
           exit(1);
        }
        read\_count ++;
        if (bits \equiv 16 \land is\_big\_endian) swap\_all\_bytes(n\_points);
        if (bits \equiv 8)
          for_int_from_to (i, 0, n_points - 1) {
             points[i].x \leftarrow pointsmall[i].x;
             points[i].y \leftarrow pointsmall[i].y;
        int n \leftarrow n\_points - 1;
        PSLA\_from\_points(n\_points);
        int hulledges[MAXN + 1];
        int hullsize \leftarrow upper\_hull\_PSLA(n, hulledges);
        P_{\text{-}}matrix P;
        compute\_lex\_smallest\_P\_matrix(\&P, n, hulledges, hullsize);
        compute\_fingerprint(\&P, n);
        printf("%s:\n", fingerprint);
     close(databasefile);
   }
```

## 17 Things to consider

- 1. The -exclude option does not currently work with the parallelization through *splitlevel*. (This combination of input parameters is checked.)
- 2. Does the enumeration of PSLAs work in constant amortized time (CAT)? Test this experimentally by a loop counter.
- 3. Enumerate PSLAs for which the corresponding AOT has a given symmetry. In connection with the PSLAs without regard to symmetries, which are known up to 16 lines (17 points), this would lead to counts of AOTs with up to 17 points without much computational effort. (The current record is 13 points).
- 4. Projective types of PSLAs, projective AOTs.
- 5. Better drawings of PSLAs.
- 6. Selective exploration of subtrees. Goal-directed search for particular examples. Can be implemented by definining further exhusion criteria, see Section 14.1.
- 7. Entropy encoding of PSLAs?

Table of contents 29

8. Using inverse-PSLA makes *screening* slower! It is only good if combined with screening one level before! Computing *inverse\_PSLA* one level before *max\_n* costs almost nothing.

9. The succ and pred arrays could be implemented as one-dimensional arrays. On some computers, 1d was clearly slower, by about 10 %. On others, there was only a small variation, less than the variation between runs of the same program.

#define SUCC\_ALTERNATE(i,j)  $succ[(i) \ll 4 \mid (j)]$  /\* A shift of 4 is sufficient for MAXN + 1  $\equiv$  16 \*/

#### List of Refinements

```
(Check for exclusion and set the flag is_excluded 21 57) Used in chunk 18.
(Compare orientation tests 61) Used in chunk 60.
Core subroutines for recursive generation 15 \ Used in chunk 6.
(Determine the matched length matched_length 24) Used in chunk 21.
Determine the result parameters rotation_period, has_mirror_symmetry, has_fixed_vertex, by analyzing the set
    of remaining candidates 45 \ Used in chunk 43.
Further processing of the AOT 58 59 60 63 64 \ Used in chunk 18.
Gather statistics about the AOT, collect output 53 \ Used in chunk 18.
Get the next excluded decimal code from the exclude-file 23 \rangle Used in chunks 21 and 22.
Global variables 5 12 20 39 50 51 70 Used in chunk 6.
Include standard libaries 10 74 \ Used in chunk 6.
Indicate Progress 19 \rightarrow Used in chunk 18.
Initialize statistics and open reporting file 52 \ Used in chunk 6.
Open the exclude-file and read first line 22 \ Used in chunk 13.
Parse the command line 13 \rangle Used in chunk 6.
Print PSLA-fingerprint 36\ \rangle Used in chunk 59.
\langle Process candidate c, keep in list and advance new_candidates if equal; reset new_candidates if better value
    than current_min is found 42 \rangle Used in chunk 41.
\langle Process candidate c, keep in list and advance new_candidates if successful; return false if better value than
    target_value is found 44 \rangle Used in chunk 43.
(Process the PSLA; return if excluded 18) Used in chunk 15.
Read all point sets of size n_{-}max + 1 from the database and process them 76 \ Used in chunk 6.
Report statistics 54 55 \ Used in chunk 6.
Screen one level below level n_{-}max 49 \ Used in chunk 15.
Screening procedures 47 \rangle Used in chunk 43.
Start the generation 16 \ Used in chunk 6.
Subroutines 27 28 30 31 33 34 35 38 40 41 43 67 69 71 73 75 77 Used in chunk 6.
Types and data structures 4 9 66 72 \ Used in chunk 6.
\langle \text{ Update counters } 17 \rangle Used in chunk 15.
```
