NumPSLA, a program for enumerating pseudoline arrangements and abstract order types

The purpose of this program is to enumerate ORIENTED abstract order types. (sometimes also called generalized configuration or a pseudoconfiguration)

The program enumerates the objects without repetition and with negligible storage.

We consider nondegenerate cases only: no three points on a line.

We abbreviate oriented abstract order type by OAOT.

(For statistics, can still report only one orientation of two mirror types)

0.1 Pseudoline arrangements and abstract order types

We consider everything *oriented*, i.e., the mirror object can be isomorphic or not. Also, only *simple*: No three curves through a point.

A projective pseudoline arrangement (PSLA) is a family of centrally symmetric closed Jordan curves on the sphere such that any two curves intersect in two points, and they intersect transversally at these points.

An affine PSLA is a family of Jordan curves in the plane that go to infinity at both ends and that intersect pairwise exactly once, and they intersect transversally at these points.

An x-monotone PSLA (wiring diagram, primitive sorting network) is an affine PSLA with x-monotone curves

We consider two objects as equivalent under deformation by orientation-preserving isotopies of the sphere, or the plane, respectively. (An x-monotone PSLA must remain x-monotone throughout the deformation.)

A marked OAOT is an OAOT with a marked point on the convex hull.

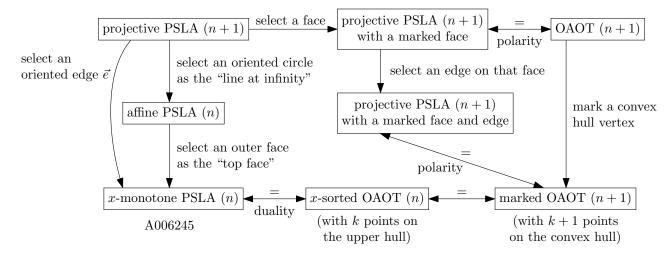

Figure 1: Relations between different concepts. There are different paths from the top left to the bottom right, which apply specialization or geometric reinterpretation in different order.

See Aichholzer and Krasser, Abstract order type extension and new results on the rectilinear crossing number. Comput. Geom. 36 (2007), 2–15, Table 1.

The main program 2

The last column counts the objects that the program actually enumerates one by one (almost, because we try to apply shortcuts). These numbers are known up to n = 15. For example, to get the 158,830 AOTs with 9 points, we go through all 1,232,944 xPSLAs with 8 pseudolines.

```
\#OAOT = 2 \times \#AOT - \#mirror-symmetric AOT [A006246]
```

#AOT equals the number of simple projective pseudoline arrangements with a marked cell.

According to OEIS, three different sequences give "the number of primitive sorting networks on n elements": A006245, A006246, A006248.

1 The main program

```
#define MAXN 15
                           /* The maximum number of pseudolines for which the program will work. */

      \langle \text{ Report statistics 52} \rangle;
#endif
     return 0;
```

1.1 Preprocessor switches

The program has the enumeration procedure at its core, but it can be configured to perfom different tasks, by setting preprocessor switches at compile-time.

We assume that the program will anyway be modified and extended for specific counting or enumeration tasks, and it makes sense to set these options at compile-time.

(Other options, which are less permanent, can be set by command-line switches.)

```
#define enumAOT 1 /* purpose is enumeration of AOTs */
    /* Other purposes might be enumeration of PSLAs */
#define readdatabase 0 /* version for reading point sets of the order-type database */
#define generatelist 0 /* List all PSLAs plus their IDs, as preparation for generating exclude-files of nonrealizable AOTs, requires enumAOT ≡ 1. */
#define profile 1 /* gather statistics and profiling information */

```

2 Representations of pseudoline arrangements

Here is an x-monotone pseudoline arrangement with n=5 pseudolines, together with a primitive graphic representation as produced by the program $print_wiring_diagram$:

Pseudoline 1 starts topmost and ends bottommost. On the right end, the order of all pseudolines is reversed. There is an imaginary pseudoline 0 of very negative slope that intersects all other pseudolines from top to bottom at the very left and again intersects all pseudolines from bottom to top at the very right.

2.1 The local sequences matrix and its inverse

Here is a representation as a two-dimensional array, indicating for each pseudoline i the sequence P_i of crossings with the other lines.

local sequences matrix

Recursive Enumeration 5

```
\begin{array}{lll} P_0 = [1,2,3,4,5] & \bar{P}_0 = [-,0,1,2,3,4] \\ P_1 = [0,4,5,3,2] & \bar{P}_1 = [0,-,4,3,1,2] & B_1 = [0,0,0,0,0] \\ P_2 = [0,3,4,5,1] & \bar{P}_2 = [0,4,-,1,2,3] & B_2 = [0,0,0,0,1] \\ P_3 = [0,2,4,5,1] & \bar{P}_3 = [0,4,1,-,2,3] & B_3 = [0,1,0,0,1] \\ P_4 = [0,2,3,1,5] & \bar{P}_4 = [0,3,1,2,-,4] & B_4 = [0,1,1,1,0] \\ P_5 = [0,2,3,1,4] & \bar{P}_5 = [0,3,1,2,4,-] & B_5 = [0,1,1,1,1] \end{array}
```

The first row and the first column are determined. Each row has n elements. We also use the data structure for an inverse array \bar{P} , which is essentially the inverse permutation of the rows. The j-th element of \bar{P}_i gives the position in P_i where the crossing with j occurs. The diagonal entries are irrelevant. The column indices in \bar{P} range from 0 to n; therefore we define the rows to have maximum length MAXN + 1.

```
\langle \text{Types and data structures 4} \rangle + \equiv
```

```
\mathbf{typedef} \ \mathbf{int} \ \mathbf{PSLA} \ [\mathbf{MAXN}+1] \ [\mathbf{MAXN}+1];
```

2.2 Linked representation

For modifying and extending PSLAs, it is best to work with a linked representation.

Point (j, k) describes the crossing with line k along the line j. SUCC(j, k) and PRED(j, k) point to the next and previous crossing on line j. For (k, j) we get the corresponding information for the line k. In the example, we have SUCC(2,3) = 5 and accordingly PRED(2,5) = 3.

The infinite rays on line j are represented by the additional line 0: SUCC(j,0) is the first (leftmost) crossing on line j, and PRED(j,0) is the last crossing. The intersections on line 0 are cyclically ordered $1, \ldots, n$. Thus, $SUCC(0,i) \leftarrow i+1$ and SUCC(0,n)=1.

The program works with a single linked-list representation, which is stored in the global arrays *succ* and *pred*. A single pair of these arrays is sufficient for the whole program.

```
#define SUCC(i,j) succ[i][j] /* access macros */
#define PRED(i,j) pred[i][j]
#define LINK(j,k1,k2)

{ /* make crossing with k_1 and k_2 adjacent on line j */
SUCC(j,k1) \leftarrow k2;
PRED(j,k2) \leftarrow k1;
}

(Global variables 7 \rangle +\equiv
int succ[\mathbf{MAXN} + 1][\mathbf{MAXN} + 1];
int pred[\mathbf{MAXN} + 1][\mathbf{MAXN} + 1];
```

3 Recursive Enumeration

We extend an x-monotone pseudoline arrangement of n-1 lines 1, ..., n-1, by threading an additional line n through it from the bottom face to the top face. The new line gets the largest slope of all lines.

Line 0 crosses the other lines in the order 1, 2, ..., n.

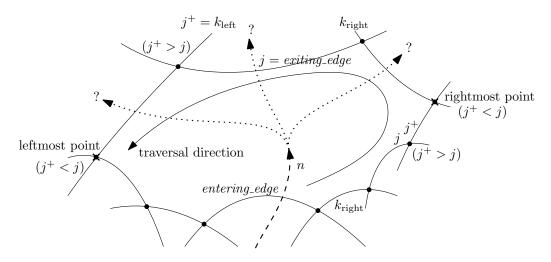

Figure 2: Threading line n through a face

Recursive Enumeration 6

```

4 Handling the exclude-file

The array $excluded_code[3...excluded_length]$ contains the decimal code of the next PSLA that should be excluded from the enumeration. During the enumeration, the decimal code of the currently visited tree node (as stored in localCountPSLA) agrees with $excluded_code$ up to position $matched_length$.

It is assumed that the codes in the exclude-file are sorted in strictly increasing lexicographic order, and no code is a prefix of another code.

To give an example, here are a few lines from the middle of the file exclude10.txt:

```
1.3.7.12.9.17.45
1.3.7.12.9.18.35
1.3.7.12.9.18.37
1.3.7.12.9.19
1.3.7.12.9.20
1.3.7.12.9.21.36
1.3.7.12.9.21.37
```

NOTE: As currently implemented, the handling of the exclude-file does not work together with the parallelization through the *splitlevel* option. This is not checked.

```
7 ⟨Global variables 7⟩ +≡
unsigned excluded_code [MAXN +3];
int excluded_length ← 0;
int matched_length ← 0; /* These initial values will never lead to any match. */
FILE *exclude_file;
char exclude_file_line [100];
```

```
\P (Check for exclusion and set the flag is_excluded 18) \equiv
   boolean is\_excluded \leftarrow false;
   \textbf{if} \ (n \equiv matched\_length + 1 \land localCountPSLA[n] \equiv excluded\_code[n]) \ \{ \\
     matched\_length \leftarrow n;
                                /* one more matching entry was found. */
     if (matched\_length \equiv excluded\_length) {
                                                        /* skip this PSLA and the whole subtree */
        is\_excluded \leftarrow true;
        (Get the next excluded decimal code from the exclude-file 20)
        (Determine the matched length matched_length 21)
This code is used in chunk 13.
\P\langle \text{Open the exclude-file and read first line 19} \rangle \equiv
   exclude\_file \leftarrow fopen(exclude\_file\_name, "r");
   (Get the next excluded decimal code from the exclude-file 20)
   matched\_length \leftarrow 2;
This code is used in chunk 8.
\P I don't know why the following program piece is so badly formatted by cweave.
\langle Get the next excluded decimal code from the exclude-file 20 \rangle \equiv
  do \{ if (fscanf(exclude\_file, "%s\n", exclude\_file\_line) \neq EOF) \} \{ char *str1 \leftarrow exclude\_file\_line; \} 
  char *token, *saveptr;
   excluded\_length \leftarrow 2;
  while (true) { token \leftarrow strtok\_r(str1, ".", &saveptr);
  if (token \equiv \Lambda) break;
   assert ( excluded\_length < MAXN +3-1 );
   excluded\_code[++excluded\_length] \leftarrow atoi(token);
   str1 \leftarrow \Lambda; \} 
  else {
                                  /* end of file reached. */
     excluded\_length \leftarrow 0;
     fclose(exclude_file);
                                                /* patterns longer than n_{-}max are filtered. */
  while (excluded\_length > n\_max);
This code is used in chunks 18 and 19
\P (The following program piece could be accelerated if the exclude-file would not store every decimal code
completely but indicate only the deviation from the previous code.)
\langle Determine the matched length matched_length 21 \rangle \equiv
   matched\_length \leftarrow 2;
   while (excluded\_code[matched\_length + 1] \equiv localCountPSLA[matched\_length + 1] \land matched\_length <
          excluded\_length \land matched\_length < n)
     matched\_length ++;
This code is used in chunk 18.
5
      Conversion between different representations
    Convert from linked list to array.

This code is used in chunk 2.

¶ The inverse PSLA matrix \bar{P} gives the following information: $\bar{P}_{jk} = p$ if the intersection between line j and line k is the p-th intersection on line j (p = 0, ..., n - 1). This is used to answer orientation queries about the pseudoline arrangement, and about the dual point set, see Section 1.9.

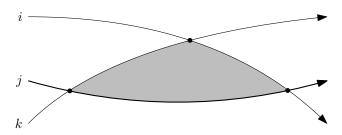

```
4 \langle \text{Subroutines 23} \rangle +\equiv
\mathbf{void} \ convert\_to\_inverse\_PS\_array(\mathbf{PSLA} * \bar{P}, \mathbf{int} \ n)
{
\mathbf{int} \ j \leftarrow 1;
\mathbf{for\_int\_from\_to} \ (i,0,n) \ \{
\mathbf{for\_int\_from\_to} \ (p,0,n-1) \ \{
(*\bar{P})[i][j] \leftarrow p;
j \leftarrow \mathsf{SUCC}(i,j);
}
j \leftarrow 0; /* j starts at 0 except for the very first line. */
}
```

6 The orientation predicate

We compute the orientation predicate in constant time from the inverse permutation array \bar{P} . It is a **boolean** predicate that returns true if the points i, j, k are in counterclockwise order. It works only when the three indices are distinct.

It is computed by comparing the intersections on line j.

If i < j < k, this predicate is *true* if the intersection of lines i and k lies above line j. When i, j, k are permuted, the predicate must change according to the sign of the permutation. For documentation purposes, we specify an expression $getOrientation_explicit$ that distinguishes all 3! possibilities in which the indices i, j, k can be ordered. getOrientation is a simpler, equivalent, expression.

```
25 #define getOrientation\_explicit(\bar{P}, i, j, k)   (i < j \land j < k ? \bar{P}[i][j] > \bar{P}[i][k] : i < k \land k < j ? \bar{P}[i][j] > \bar{P}[i][k] : j < i \land i < k ? \bar{P}[i][j] < \bar{P}[i][k] : j < k \land k < i ? \bar{P}[i][j] > \bar{P}[i][k] : k < j \land j < i ? \bar{P}[i][j] > \bar{P}[i][k] : k < i \land i < j ? \bar{P}[i][j] < \bar{P}[i][k] : 0) #define getOrientation(\bar{P}, i, j, k) ((i < j) \oplus (j < k) \oplus (\bar{P}[j][i] > \bar{P}[j][k]))
```

 \P extreme points from the PSLA.

This is easy; we just scan the top face. We know that 0, 1, and n belong to the convex hull. 0 represents the line at ∞).

The input is taken from the global variable *succ*. (pred is not used.)

7 Unique identifiers, accession numbers, Dewey decimal notation

The recursive enumeration algorithm imposes an implicit tree structure on PSLAs: the parents of a PSLA with n lines is the unique PSLA on n-1 lines from which it is generated. We number the children of each node in the order in which they are generated, starting from 1. The sequence of labels on the path from the root to a node gives a unique identifier to each node in the tree. (This is, however, specific to details of the enumeration algorithm: in which order edges are considered for crossing in the insertion, the choice of lexicographic criterion.)

The purpose of this scheme is that it allows to identify a PSLA even if we parallelize the computation, and one thread of the program only visits certain branches of the tree.

```
    27 ⟨Global variables 7⟩ +≡
        unsigned localCountPSLA[MAXN +3];
    28 ¶ ⟨Subroutines 23⟩ +≡
        void print_id(int n)
```

```
printf("\%d", localCountPSLA[3]); \\ \textbf{for\_int\_from\_to} \ (i,4,n) \ \ printf(".\%d", localCountPSLA[i]); \\ \}
```

8 Output

¶ Prettyprinting of a wiring diagram. Fill a buffer of lines columnwise from left to right.

```
#define TO_CHAR(i) ((char)((i < 10 ? (int) '0' : ((int) 'A' - 10)) + i))
\langle \text{ Subroutines } 23 \rangle + \equiv

```

Output 12

```
 \begin{array}{c} \mathbf{for\_int\_from\_to} \ (j,1,n-2) \ \ printf("\%c", \mathtt{TO\_CHAR}((*P)[i][j])); \\ \} \\ \} \end{array} \}
```

8.1.1 A more compact fingerprint

Sufficient to know

This code is used in chunk 53.

```
B_i[j] = 1 if P_i[j] < i, see Felsner, Chapter 6.
```

binary arrays B_1, \ldots, B_n . The first column is fixed. The first row B_1 and the last row B_n is fixed, and they need not be coded. Also, since row B_i contains i-1 ones, we can omit the last entry per row, since it can be reconstructed from the remaining entries. Thus we encode the $(n-2) \times (n-2)$ array obtained removing the bordere from the original $n \times n$ array.

We code 6 bits into an ASCII symbol, using the small and capital letters, the digits, and the symbols + and

Since we use this encoding for the case when n is known, we need not worry about terminating the code. (Replace matrices would offer even more savings.)

```
#define FINGERPRINT_LENGTH 30 /* enough for 13 \times 13 bits plus terminating null */ \langle Global variables 7\rangle += char fingerprint[FINGERPRINT_LENGTH];
```

```
\P\langle \text{Subroutines } 23 \rangle + \equiv

     printf("\%s:",fingerprint);
```

9 Abstract order types

9.1 Lexmin for PSLA representation

In order to generate every AOT only once, we check whether the representation is smallest among all PSLAs that produce AOTs, that are *equivalent* by rotation and reflection.

Lexicographically smallest. We have to try all "boundary points" (?) as pivot points. The average number of extreme vertices is slightly less than 4. It does not pay off to shorten the loop considerably. (The average squared face size matters!)

To determine !!!! whether a PSLA is the lex-smallest among all PSLAs representing an AOT, we scan the PSLA matrix row-wise *from right to left*. In comparison with the more natural left-to-right order, this gives, experimentally, a quicker way to eliminate tentative PSLA than the left-to-right order.

```
36
     \langle \text{Global variables } 7 \rangle + \equiv
        int Sequence[MAXN +1][MAXN +1];
            /* Sequence [r][p] gives the p-th crossing on the r-th hull edge. */
        int new_label[MAXN +1][MAXN +1]; /* When the r-th hull edge is used in the role of line 0,
             new\_label[r][j] gives index that is use for the (original) line j. */
        int candidate[2*(MAXN +1)];
                                                   /* list of candidates, gives index r into hulledges */
        int current\_crossing[2*(MAXN +1)];
                                                           /* indexed by candidate number */
        int P_1_n-forward [MAXN +1];
        int P_1_n_reverse[\mathbf{MAXN} + 1];
     \P\langle \text{Subroutines } 23 \rangle + \equiv
        \mathbf{void} \ \ prepare\_label\_arrays(\mathbf{small\_int} \ \ n, \mathbf{small\_int} \ *hulledges, \mathbf{small\_int} \ \ hullsize)
           for_int_from_to (r, 0, hullsize - 1)
             if (P_{-1} - reverse[r] \equiv P_{-1} - reversd[0] \lor (r > 0 \land P_{-1} - reversd[r] \equiv P_{-1} - reversd[0])) {
                    /* otherwise not needed. */
                int line0 \leftarrow hulledges[r];
                new\_label[r][line\theta] \leftarrow 0;
                int i \leftarrow (r < hullsize - 1)? hulledges[r + 1] : 0; /* 0 \equiv hulledges[0] */
                for_int_from_to (p, 1, n)  {
                   new\_label[r][i] \leftarrow p;
                   Sequence[r][p] \leftarrow i;
                   i \leftarrow \texttt{SUCC}(line\theta, i);
                }
             }
        }
```

9.2 Compute the lex-smallest representation

The input is taken from the global *succ* and *pred* arrays. The function assumes that *hulledges* and *hullsize* have been computed.l)

```
\langle \text{Subroutines } 23 \rangle + \equiv
        void compute\_lex\_smallest\_PSLA(\mathbf{PSLA}*P,\mathbf{small\_int}\;n,\mathbf{small\_int}*hulledges,\mathbf{small\_int}\;hullsize)
              for_int_from_to (q, 0, n - 1) (*P)[0][q] \leftarrow q + 1;
                                                                                                                                                                                       /* row 0 */
              for_int_from_to (r, 0, hull size - 1) P_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_n_{-1}_{n_{-1}_{n_{-1}}_n_{-1}_n_{-1}_{n_{-1}_{n_{-1}}_n_{-1}_{n_{-1}_{n_{-1}}_n_{-1}_n_{-1}_n_{-1}_{n_{-1}_{n_{-1}}_{n_{-1}_{n_{-1}}_{n_{-1}_{n_{-1}}_{n_{-1}_{n_{-1}}_{n_{-1}_{n_{-1}}_{n_{-1}_{n_{-1}}_{n_{-1}_{n_{-1}}_{n_{-1}_{n_{-1}}_{n_{-1}_{n_{-1}}_{n_{-1}_{n_{-1}}_{n_{-1}_{n_{-1}}_{n_{-1}_{n_{-1}}_{n_{-1}_{n_{-1}}_{n_{-1}_{n_{-1}}_{n_{-1}_{n_{-1}}_{n_{-1}_{n_{-1}}_{n_{-1}_{n_{-1}}_{n_{-1}_{n_{-1}}_{n_{-1}_{n_{-1}}_{n_{-1}_{n_{-1}}_{n_{-1}_{n_{-1}}_{n_{-1}_{n_{-1}}_{n_{-1}_{n_{-1}}_{n_{-1}_{n_{-1}}_{n_{-1}_{n_{-1}}_{n_{-1}}_{n_{-1}_{n_{-1}}_{n_{-1}_{n_{-1}}_{n_{-1}}_{n_{-1}_{n_{-1}}_{n_{-1}}_{n_{-1}_{n_{-1}}_{n_{-1}}_{n_{-1}_{n_{-1}}_{n_{-1}_{n_{-1}}_{n_{-1}}_{n_{-1}_{n_{-1}}_{n_{-1}_{n_{-1}}_{n_{-1}_{n_{-1}}_{n_{-1}}_{n_{-1}}_{n_{-1}_{n_{-1}}_{n_{-1}}_{

       (*P)[p][n-q] \leftarrow current\_min;
                                            /* could enter a shortcut as soon as numcandidates \equiv 1 */
  }
}
```

 \P The list of candidates is scanned and simultaneously overwritten with new values.

 $\langle \text{Process candidate } c, \text{ keep in list and advance } new_candidates \text{ if equal; reset } new_candidates \text{ if better value } than <math>current_min \ 39 \rangle \equiv int \ r \leftarrow candidate [c]; int \ i \leftarrow Sequence [r][pos]; /* We are proceeding on line i */ int \ j \leftarrow current_crossing [c]; j \leftarrow reversed ? SUCC(i, j) : PRED(i, j);$

 \P The output parameters have only a meaning if the test returns $true.\ has_fixpoint$ is only set if the PSLA is mirror-symmetric.

We scan the entries of P row-wise from right to left. We maintain a list of solutions, which are still candidates to be lex-smallest. Initially we have $2 \times hullsize$ candidates, hullsize "forward" candidates and the same number of mirror-symmetric, reversed candidates.

Candidates $0 \dots numcandidates_forward-1$ are forward candidates. The remaining candidates up to numcandidates-1 are reverse (mirror) candidates.

If information about mirror symmetry is not necessary, then the mirror candidates can be omitted.

9.3 Streamlined version

Fast screening of candidates

Let i and j be two consecutive edges on the upper envelope. The quantity Q(i, j) is defined as follows, see Figure 3a.

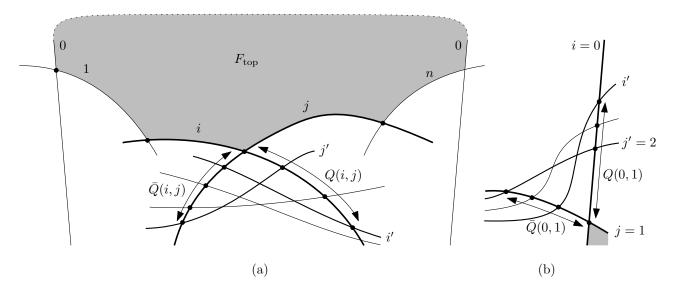

Figure 3: (a) An example with Q(i,j)=4 and $\bar{Q}(i,j)=5$; (b) an example with $Q(0,1)=\bar{Q}(0,1)=4$

Let i' = PRED(i, j). Walk on line i to the right (by SUCC) from the intersection between i and j until meeting the intersection with i'. Then Q(i, j) is the number of visited points on i, including the endpoints. This convention ensures that Q(i, j) is the value P_{1n} when line i is chosen to play the role of line 0, (and j will become line 1). In the walk along i, we may cross line 0 and wrap around to the left end.

The quantity Q(i, j) is defined with switched roles of i and j and with left and right exchanged, and it gives the value P_{1n} in the mirror situation (the *backward* direction) when line j is chosen to play the role of line 0: Let j' = SUCC(i, j). Walk on line j to the left (by PRED) until meeting line j'.

We apply this definition two all pairs (i, j) of consecutive edges on the upper envelope, starting with (0, 1) and ending with (n, 0). (The last pair is the only pair with i > j.)

The numbers Q(i,j) and $\bar{Q}(i,j)$ are between 2 and n, and $Q(i,j)=2 \iff \bar{Q}(i,j)=2$.

For (i,j) = (0,1), the wedge between lines i and j appears actually at the bottom right of the wiring diagram, see Figure 3b. Here we have $Q(0,1) = PRED(1,0) = P_{1n}$, since this is the original situation where line 0 is where it should be. Similarly, for (i,j) = (n,0), we have to look at the bottom left corner.

Our primary criterion in comparing candidates is P_{1n} which is given by Q(i,j) and $\bar{Q}(i,j)$ for the pairs (i,j) of consecutive edges on the upper envelope. This has to be compared against. Q(0,1).

¶ Screen candidates by comparing the leading entry P_{1n} ,

Compute the leading entry P_{1n} for all candidates directly, without first computing the $label_arrays$. The $label_arrays$ are computed afterwards (if at all), and only those that are still necessary. This saves about 20% of the runtime for enumerating AOTs. If $P_{1n}=2$ for line 0, the screening has no effect, but otherwise there is a high chance for finding a smaller value P_{1n} for some of the other candidates.

[Observation. The relative frequence of P_{1n} over all PSLAs is about 26% for 2 and n, about 11% for 3 and n-1 and decreases towards the middle values. The symmetry can be explained as follows. An xPSLA is essentially a projective oriented PSLA with a marked angle. Going to an adjacent angle and mirroring the PSLA exchanges a with n+2-a.

The following program treats each forward candidate i together with the corresponding mirror candidate j. it uses the condition $Q(i,j)=2 \iff \bar{Q}(i,j)=2$ to shortcut the computation. (not sure if it brings any advantage.)

For example there are 18,410,581,880 PSLAs with n=10 lines. Of these, only 5,910,452,118 pass the screening test. Eventually, only 2,343,203,071 PSLA are really lex-min, and this is the number of AOTs that we really want.

```
\langle \text{Subroutines } 23 \rangle + \equiv

        } while (i2 \neq j');
        if (a < P_1_n_{forward}[0]) return false;
        P_1_n_reverse[r_next] \leftarrow a;
     return true;
```

¶ More effective screening at the previous level.

Rather than generating many PSLAs with n lines and eliminating them by screening, it is better not to generate them at all, or to generate only those that have a change of surviving the screening test.

To do this, we apply a test at the previous level.

When adding a new line n, the quantities Q(i,j) can change in a few ways.

- 1. We cut off some hull vertices. In particular, (n-1,0) will always disappear.
- 2. We generate two new hull vertices: (i, n) with $1 \le i \le n 1$, and (n, 0).
- 3. In the definition of Q(i,j), line n could take the role of i'. (or j' in the case of $\bar{Q}(i,j)$).
- 4. In the definition of Q(i,j), line n could intervene between the intersections with j and i' on line i, thus increasing Q(i,j) by 1. (or a similar situation for $\bar{Q}(i,j)$).

A very rudimentary pre-screening test has been implemented, namely for the comparison between Q(0,1) and $\bar{Q}(1,0)$:

If $\bar{Q}(0,1) < Q(1,0) - 1$ in the arrangement with n-1 lines, then there is no chance to augment this to a lex-min PSLA.

Proof: See Figure 3b. There are two cases. If line n does not intersect the segment between 1×0 and $1 \times PRED(1,0)$, then $Q(0,1) = P_{1n}$ is unchanged. $\bar{Q}(1,0)$ can increase by at most 1. Thus $\bar{Q}(1,0)$ will beat Q(1,0).

If line n intersects line 1 between 1×0 and $1 \times PRED(1,0)$, then n becomes the new $i' = PRED(1,0) = Q(0,1) = P_{1n}$, and thus P_{1n} has the maximum possible value, n, and is certainly larger than before. $\bar{Q}(1,0)$ can still increase by at most 1. Thus $\bar{Q}(1,0)$ will beat Q(1,0).

For example, with n=9 lines there are 112,018,190 PSLAs, and they generate as children 18,410,581,880 PSLAs with n=10 lines, as mentioned above. The screening test at level n=9 eliminates 22,023,041 out of the 112,018,190 PSLAs (19.66%) because they are not able to produce a lex-min AOT in the next generation. The remaining 89,995,149 PSLAs produce 15,409,623,219 offspring PSLAs with n=10 lines. as opposed to 18,410,581,880 without this pruning procedure. These remaining PSLAs are subject to the screening as before.

```
\P \langle \text{Screen one level below level } n_max | 44 \rangle \equiv
  int P_{-1}n \leftarrow PRED(1,0);
                                 /* insertion of last line n can only make this larger. */
  if (P_{-}1_{-}n > 3) {
     int a \leftarrow 2;
                            /* \equiv i' */
     int i2 \leftarrow P_{-}1_{-}n;
     while (i2 \neq 2) {
                             /* compute a by running along j \equiv 1 */
       i2 \leftarrow PRED(1, i2);
           /* Now P_{-1}-n_reverse \equiv a but insertion of line n could increase this by 1. */

This code is used in chunk 13.

11 Data structures for abstract order types

\mathbb{I} λ -matrices.

In this program, entries Λ_{ijk} of the large matrix are only ever accessed for i < j < k. For more general access, we provide the macro get_entry_large . It would be possible to save space by a more elaborate indexing function into a one-dimensional array.

natural labeling around the *pivot* point, which is assumed to lie on the convex hull.

```
56 #define entry\_small(A, i, j) (A)[i][j]
```

 \P More type definitions.

This code is used in chunk 53.

```
typedef uint_fast8_t XXsmall_matrix_entry; /* suffices up to n = 255 + 1 */
typedef int_fast8_t XXsmall_int; /* suffices for n */
typedef boolean large_matrix_entry;
typedef unsigned small_matrix_entry;
typedef int small_int; /* simpler and maybe even faster? */
typedef small_matrix_entry small_matrix [MAXN +1][MAXN +1];
typedef large_matrix_entry large_matrix [MAXN +1][MAXN +1];
```

¶ Generating the Λ -matrix. Only for testing purposes. Assumes natural ordering. Assumes general position. Works by plucking points from the convex hull one by one.

```
 \begin{array}{l} \langle \operatorname{Subroutines} \ 23 \rangle +\equiv \\ \mathbf{void} \ \operatorname{copy\_small}(\mathbf{small\_matrix} \ *A, \mathbf{small\_matrix} \ *B, \mathbf{small\_int} \ n) \\ \{ \\ \mathbf{for} \ (\mathbf{small\_int} \ i \leftarrow 0; \ i < n; \ i++) \\ \mathbf{for} \ (\mathbf{small\_int} \ j \leftarrow 0; \ j < n; \ j++) \ \operatorname{entry\_small}(*B, i, j) \leftarrow \operatorname{entry\_small}(*A, i, j); \\ \} \\ \mathbf{void} \ \operatorname{convert\_small\_to\_large}(\mathbf{small\_matrix} \ *A, \mathbf{large\_matrix} \ *B, \mathbf{small\_int} \ n) \\ \{ \\ \mathbf{small\_matrix} \ \operatorname{Temp}; \\ \operatorname{copy\_small}(A, \& \operatorname{Temp}, n); \quad /* \ \text{the small matrix} \ \operatorname{Temp} \ \text{will be destroyed} \ */ \\ \mathbf{for} \ (\mathbf{small\_int} \ i \leftarrow 0; \ k < n; \ k++) \\ \mathbf{for} \ (\mathbf{small\_int} \ i \leftarrow k+1; \ i < n; \ i++) \\ \mathbf{for} \ (\mathbf{small\_int} \ j \leftarrow i+1; \ j < n; \ j++) \quad /* \ k < i < j \ */ \\ \{ \\ \mathbf{entry\_small}(\operatorname{Temp}, i, k) < \operatorname{entry\_small}(\operatorname{Temp}, j, k)) \ \{ \\ \operatorname{entry\_small}(\operatorname{Temp}, i, j) --; \\ \end{array}
```

```
 \begin{array}{c} (*B)[k][i][j] \leftarrow (*B)[i][j][k] \leftarrow (*B)[j][k][i] \leftarrow true; \\ (*B)[k][j][i] \leftarrow (*B)[i][k][j] \leftarrow (*B)[j][i][k] \leftarrow false; \\ \} \\ \textbf{else } \{ \\ entry\_small(Temp, j, i) --; \\ (*B)[k][i][j] \leftarrow (*B)[i][j][k] \leftarrow (*B)[j][k][i] \leftarrow false; \\ (*B)[k][j][i] \leftarrow (*B)[i][k][j] \leftarrow (*B)[j][i][k] \leftarrow true; \\ \} \\ \} \\ \} \end{array}
```

12 Auxiliary routines and conversion to other formats

¶ Input: PSLA with n lines 1..n plus line 0 "at ∞ ". Output: small λ -matrix B for AOT on n+1 points. Line at ∞ corresponds to point 0 on the convex hull.

```
\langle \text{Subroutines } 23 \rangle + \equiv
   void convert\_to\_small\_lambda\_matrix(small\_matrix *B, int n)
     for_int_from_to (i, 0, n) {
        (*B)[i][i] \leftarrow 0;
     for_int_from_to (i, 1, n) {
        int level \leftarrow i-1;
                                  /* number of lines above the crossing */
        (*B)[0][i] \leftarrow level;
        (*B)[i][0] \leftarrow n-1-level;
        int j \leftarrow SUCC(i, 0);
        while (j \neq 0) {
           if (i < j) {
              (*B)[i][j] \leftarrow level;
              level++;
           else {
              level--;
              (*B)[i][j] \leftarrow n-1-level;
           j \leftarrow \mathtt{SUCC}(i, j);
   }
```

13 Reading from the Order-Type Database

For simplicity, we work only with numbers in the 16-bit format. Inputs in 8-bit formats are converted.

```
61 \langle Global variables 7 \rangle + \equiv
struct \{ \ /* \ 16\text{-bit unsigned coordinates: } */
uint16\_tx, y;
\} \ points[\mathbf{MAXN} + 1];
struct \{ \ /* \ 8\text{-bit unsigned coordinates: } */
uint8\_tx, y;
\} \ pointsmall[\mathbf{MAXN} + 1];
```

13.1 Orientation test for points

The return value of orientation_test is positive for counterclockwise orientation of the points i, j, k.

```
62 \langle \text{Subroutines 23} \rangle + \equiv \\ \text{large\_int } orientation\_test(\text{int } i, \text{int } j, \text{int } k) \\ \{ \\ \text{large\_int } a \leftarrow points[j].x - (\text{large\_int}) \ points[i].x; \ /* \ \text{range } -65535..65535 \ */ \ \end{cases}
```

```
\begin{aligned} & \mathbf{large\_int} \ b \leftarrow points[j].y - (\mathbf{large\_int}) \ points[i].y; \\ & \mathbf{large\_int} \ c \leftarrow points[k].x - (\mathbf{large\_int}) \ points[i].x; \\ & \mathbf{large\_int} \ d \leftarrow points[k].y - (\mathbf{large\_int}) \ points[i].y; \\ & \mathbf{return} \ a*d - b*c; \\ \end{aligned}
```

¶ Intermediate results can be almost 2^{32} in absolute value, and they have signs. The final value is the signed area of the parallelogram spanned by 3 points. Thus it can also be almost 2^{32} in absolute value. 32 bits are not enough to be safe. We use 64 bits.

```
63 ⟨Types and data structures 4⟩ +≡

typedef int_least64_t large_int; /* for intermediate calculations */
```

13.2 Turn point set with coordinates into PSLA

We insert the lines one by one into the arrangement. This is simular to the insertion of line n in the recursive enumeration procedure. The difference is that we don't try all possibilities for the edge through which line n exits, but we choose the correct edge the by orientation test. By the zone theorem, the insertion of line n takes O(n) time.

We have n points. The first point (point 0) is on the convex hull and the other points are sorted around this point. We get a PSLA with n-1 pseudolines.

```
\langle Subroutines 23\rangle + \equiv
   void insert_line(int n);
   void PSLA\_from\_points(\mathbf{int} \ n)
   {
     LINK(1, 0, 2);
     LINK(1, 2, 0);
     LINK(2, 0, 1);
     LINK(2, 1, 0);
     LINK(0, 1, 2);
          /* LINK(0, 2,3) and LINK(0, 3,1) will be established shortly in the first recursive call. */
      for_int_from_to (i, 3, n-1) insert_line(i);
   void insert\_line(\mathbf{int} \ n)
     LINK(0, n-1, n);
     LINK(0, n, 1);
     int entering_edge \leftarrow 0, j \leftarrow 0, j^+ \leftarrow 0;
     int k_{\text{left}}, k_{\text{right}};
      while (1) {
        while (j^+ > j) { /* find right vertex of the cell */
           int j_{\text{old}}^+ \leftarrow j^+;
           j^+ \leftarrow \texttt{SUCC}(j^+, j);
           j \leftarrow j_{\text{old}}^+;
        if (j^+ \equiv 0) { /* F is unbounded */
if (j \equiv n-1) { /* F is the top face. */
              LINK(n, entering\_edge, 0); /* complete insertion of line n */
           j^+ \leftarrow j + 1;
                             /* jump to the upper ray of F */
               /* Now the crossing j \times j^+ is the rightmost vertex of the face F. j^+ is on the upper side, and if F
                 is bounded, j is on the lower side, */
        \mathbf{do} {
                     /* scan the upper edges of F from right to left and find the correct one to cross. */
            k_{\text{right}} \leftarrow j;
           j \leftarrow j^+;
           k_{\text{left}} \leftarrow j^+ \leftarrow \text{PRED}(j, k_{\text{right}});
         } while (j^+ > j \land orientation\_test(j, k_{left}, n) > 0);
```

13.3 Do the actual reading

We have to figure out the filenames and the format of the stored numbers. We assume that the order types with up to 10 points are stored in the current directory in with the original file names otypes10.b16, otypes09.b16, otypes08.b08, etc., and the order types with 11 points are stored in a subdirectory Ordertypes with names Ordertypes/ord11_00.b16...Ordertypes/ord11_93.b16.

```
Ordertypes/ord11_00.b16 ... Ordertypes/ord11_93.b16.
\langle Include standard liberies 5\rangle + \equiv
#include <fcntl.h>
#include <unistd.h>
\P\langle \text{Subroutines } 23 \rangle + \equiv
  void swap\_all\_bytes(\mathbf{int} \ n)
         /* convert numbers from little-endian to big-endian format. */
     for_int_from_to (i, 0, n-1) {
       points[i].x \leftarrow (points[i].x \gg 8) \mid (points[i].x \ll 8);
       points[i].y \leftarrow (points[i].y \gg 8) \mid (points[i].y \ll 8);
           /* Assumes 16 bits. It is important that coordinates are UNSIGNED. */
   }
\P\langle \text{Read all point sets of size } n_{-max} + 1 \text{ from the database and process them } 67 \rangle \equiv
  int n\_points \leftarrow n\_max + 1;
  int bits \leftarrow n\_points > 9 ? 16 : 8;
  char inputfile [60];
  int record\_size \leftarrow (bits/8) * 2 * n\_points;
  printf("Reading_lorder_ltypes_lof_l%d_lpoints\n", n_points);
  printf(".\n");
  printf("One\_record\_is\_%d\_bytes\_long.\n", record\_size);
  boolean is\_big\_endian \leftarrow (*(uint16\_t*)"\0\xff" < #100/);
  if (bits > 8) {
     if (is\_big\_endian) printf("This\_computer\_is\_big\_endian.\n");
     else printf("Thisucomputeruisulittle-endian.uNoubyteuswapsuareunecessary.\n");
  if (n\_points < 11) {
     snprintf(inputfile, 60, "otypes%02d.b%02d", n_points, bits);
     read_database_file(inputfile, bits, record_size, n_points, is_big_endian);
  else
     for_int_from_to (num_db, 0, 93)  {
       snprintf(inputfile, 60, "Ordertypes/ord%02d_%02d.b16", n_points, num_db);
        read_database_file(inputfile, bits, record_size, n_points, is_biq_endian);
  printf("%Ld_point_sets_were_read_from_the_file(s).\n", read_count);
This code is used in chunk 2.
\P Open and read database file and process the input points.
```

```
68 \langle \text{Subroutines 23} \rangle + \equiv long long unsigned read_count \leftarrow 0;
```

Things to consider 26

```
void read\_database\_file(\mathbf{char}*inputfile,\mathbf{int}\;bits,\mathbf{int}\;record\_size,\mathbf{int}\;n\_points,\mathbf{boolean}\;is\_big\_endian)
  printf("Reading_from_file_%s\n", inputfile);
  int databasefile \leftarrow open(inputfile, O_RDONLY);
  if (databasefile \equiv -1) {
     printf("File_could_not_be_opened.\n");
     exit(1);
  while (1) {
     ssize_t bytes_read;
     if (bits \equiv 16) bytes\_read \leftarrow read(databasefile, \&points, record\_size);
     else bytes\_read \leftarrow read(databasefile, \&pointsmall, record\_size);
     if (bytes\_read \equiv 0) break;
     if (bytes\_read \neq record\_size) {
        printf("Incomplete_file.\n");
        exit(1);
     }
     read\_count ++;
     if (bits \equiv 16 \land is\_big\_endian) \ swap\_all\_bytes(n\_points);
     if (bits \equiv 8)
        for_int_from_to (i, 0, n_points - 1) {
          points[i].x \leftarrow pointsmall[i].x;
          points[i].y \leftarrow pointsmall[i].y;
     int n \leftarrow n\_points - 1;
     PSLA\_from\_points(n\_points);
     small_int hulledges[MAXN +1];
     small_int hullsize \leftarrow upper\_hull\_PSLA(n, hulledges);
     PSLA P;
     compute\_lex\_smallest\_PSLA(\&P, n, hulledges, hullsize);
     compute\_fingerprint(\&P, n);
     printf("%s:\n", fingerprint);
  close(databasefile);
}
```

14 Things to consider

- 1. The **-exclude** option does not work with the parallelization through *splitlevel*. (This is not currently checked.)
- 2. Using inverse-PSLA makes *screening* slower! It is only good if combined with screening one level before! Computing *inverse_PSLA* one level before *max_n* costs almost nothing.
- 3. The succ and pred arrays could be implemented as one-dimensional arrays. Need to check which is faster.

```
##define SUCC_ALTERNATE(i, j) succ[i \ll 4 \mid j] /* A shift of 4 is sufficient for MAXN +1 \equiv 16 */
```

Index 30

List of Refinements

```
\langle Check for exclusion and set the flag is_excluded 18\rangle Used in chunk 13.
(Compare orientation tests 54) Used in chunk 53.
Core subroutine for recursive generation 13 \ Used in chunk 2.
Determine the matched length matched_length 21 \rangle Used in chunk 18.
Determine the result parameters, depending on the remaining candidates. 48 Used in chunk 46.
Further processing of the AOT 53 \ Used in chunk 13.
 Gather statistics about the AOT, collect output 51 \ Used in chunk 13.
Get the next excluded decimal code from the exclude-file 20 >
                                                                     Used in chunks 18 and 19.
Global variables 7 11 17 27 32 36 45 49 61 \ Used in chunk 2.
Include standard libaries 5 65 \ Used in chunk 2.
Indicate Progress 15 \ Used in chunk 13.
Initialize statistics and open reporting file 50 \ Used in chunk 2.
Open the exclude-file and read first line 19 \ Used in chunk 8.
Parse the command line 8 \ Used in chunk 2.
Print PSLA-fingerprint 34 \ Used in chunk 53.
\langle Process candidate c, keep in list and advance new_candidates if equal; reset new_candidates if better value
    than current_min 39 Used in chunk 38.
\langle Process candidate c, keep in list and advance new_candidates if successful; return false if better value than
    target_value is found 47 \ Used in chunk 46.
\langle \text{Read all point sets of size } n_{\text{-}}max + 1 \text{ from the database and process them } 67 \rangle Used in chunk 2.
Report statistics 52 \ Used in chunk 2.
Screen one level below level n_{-}max 44
                                            Used in chunk 13.
Start the generation 14 Used in chunk 2.
Subroutines 23 24 26 28 30 31 33 37 38 42 46 58 60 62 64 66 68 \ Used in chunk 2.
\langle \text{ Types and data structures 4 10 57 63} \rangle Used in chunk 2.
(Update counters 16) Used in chunk 13.
```
