December 2, 2023 at 06:58

The -exclude option.

Using inverse-PSLA makes screening SLOWER! Only good if combined with screening one level before! Computing inverse-PSLA one level before max-n costs almost nothing. (Whatever that means!)

1 Introduction

The purpose of this program is to enumerate ORIENTED abstract order types. (sometimes also called generalized configuration or a pseudoconfiguration)

Programm enumerates the objects without repetition and without much storage.

We consider nondegenerate cases only: no three points on a line.

We abbreviate oriented abstract order type by OAOT.

(For statistics, can still report only one orientation of two mirror types)

1.1 Pseudoline Arrangements and Abstract Order Types

We consider everything *oriented*, i.e., the mirror object can be isomorphic or not. Also, only *simple*: No three curves through a point.

A projective pseudoline arrangement (PSLA) is a family of centrally symmetric closed Jordan curves on the sphere such that any two curves intersect in two points, and they intersect transversally at these points.

An affine PSLA is a family of Jordan curves in the plane that go to infinity at both ends and that intersect pairwise exactly once, and they intersect transversally at these points.

An x-monotone PSLA (wiring diagram, primitive sorting network) is an affine PSLA with x-monotone curves.

We consider two objects as equivalent under deformation by orientation-preserving isotopies of the sphere, or the plane, respectively. (An x-monotone PSLA must remain x-monotone throughout the deformation.)

A marked OAOT is an OAOT with a marked point on the convex hull.

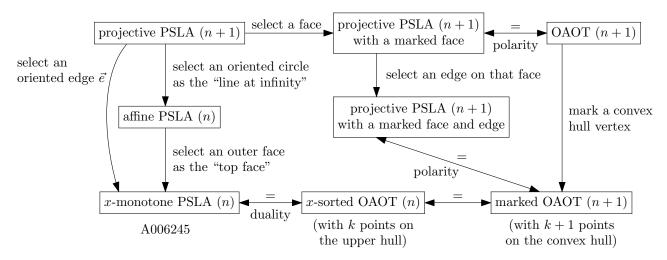

Figure 1: Relations between different concepts. There are different paths from the top left to the bottom right, which apply specialization or geometric reinterpretation in different order.

See Aichholzer and Krasser, Table 1. [A063666] [A006245] [A006247]#mirror-symmetric AOT #AOT #realizable AOT #Ox-monotonePSLA 3 1 0 0 2 4 2 2 0 0 2 8 5 3 3 0 0 3 62 6 12 16 16 0 0 908 7 135 135 0 0 28 24,698 8 0 225 3,315 3,315 0 1,232,944 9 0,01 % 825 158,830 158,817 13 112,018,190 10,635 10 14,320,182 14,309,547 $0.07\,\%$ 13,103 18,410,581,880 2,343,203,071 2,334,512,907 8,690,164 0.37%76,188 5,449,192,389,984 11 2,894,710,651,370,536 12 691,470,685,682

The last column counts the objects that the program actually enumerates one by one (almost, because we try to apply shortcuts). These numbers are known up to n = 15. For example, to get the 158,830 AOTs with 9 points, we go through all 1,232,944 xPSLAs with 8 pseudolines.

```
\#OAOT = 2 \times \#AOT - \#mirror-symmetric AOT [A006246]
```

#AOT equals the number of simple projective pseudoline arrangements with a marked cell.

According to OEIS, three different sequences give the number of primitive sorting networks on n elements: A006245, A006246, A006248.

1.2 The main program

```
#define MAXN 11
                          /* The maximum number of pseudolines for which the program will work. */
   (Include standard libaries 6)
    Types and data structures 5
    Global variables 10
   (Subroutines 22)
   \langle Core subroutine for recursive generation 12 \rangle
  int main(int argc, char *argv[])
     \langle \text{ Parse the command line } 60 \rangle;
#if readdatabase
                         /* reading from the database */
     \langle \text{Read all point sets of size } n_{-}max + 1 \text{ from the database and process them } 70 \rangle
     return 0:
#endif
\#if\ enumAOT
     (Initialize statistics and open reporting file 49);
     \langle Start the generation 13\rangle;
     \langle \text{ Report statistics 51} \rangle;
#endif
     return 0;
```

1.3 Preprocessor switches

The program has the enumeration procesure at its core, but it can be configured to perfom different tasks, by setting preprocessor switches at compile-time.

We assume that the program will anyway be modified and extended for specific counting or enumeration tasks, and it makes sense to set these options at compile-time.

(Other options, which are less permanent, can be set by command-line switches.)

See also chunks 9, 56, and 66* This code is used in chunk 3*.

 $\langle \text{ Types and data structures 5} \rangle \equiv$

typedef enum { false, true } boolean;

¶ Standard libraries

```
⟨ Include standard libaries 6⟩ ≡

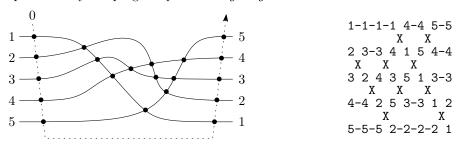

#include <stdio.h>
#include <stdint.h>
#include <stdlib.h>
#include <string.h>
#include <assert.h>
See also chunk 68*.
This code is used in chunk 3*.
```

1.4 Auxiliary macros for for-loops

```
#define for_int_from_to(x, first, last) for (int x ← first; x ≤ last; x++)
format for_int_from_to for
#define print_array(a, length, begin, separator, end)
{     /* for reporting and debugging */
     printf(begin);
     for_int_from_to(j, 0, length - 1) {
        if (j > 0) printf(separator);
        printf("%d", a[j]);
     }
     printf(end);
} /* for gcc, compile with -Wno-format-zero-length to suppress warnings */
```

1.5 Representations of Pseudoline arrangements

Here is an x-monotone pseudoline arrangement with n=5 pseudolines, together with a primitive graphic representation as produced by the program $print_wiring_diagram$:

Pseudoline 1 starts topmost and ends bottommost. On the right end, the order of all pseudolines is reversed. There is an imaginary pseudoline 0 of very negative slope that intersects all other pseudolines from top to bottom at the very left and again intersects all pseudolines from bottom to top at the very right.

The local sequences matrix and its inverse

Here is a representation as a two-dimensional array, indicating for each pseudoline i the sequence P_i of crossings with the other lines.

local sequences matrix

```
\begin{array}{lll} P_0 = [1,2,3,4,5] & \bar{P}_0 = [\text{-},0,1,2,3,4] \\ P_1 = [0,4,5,3,2] & \bar{P}_1 = [0,\text{-},4,3,1,2] & B_1 = [0,0,0,0,0] \\ P_2 = [0,3,4,5,1] & \bar{P}_2 = [0,4,\text{-},1,2,3] & B_2 = [0,0,0,0,1] \\ P_3 = [0,2,4,5,1] & \bar{P}_3 = [0,4,1,\text{-},2,3] & B_3 = [0,1,0,0,1] \\ P_4 = [0,2,3,1,5] & \bar{P}_4 = [0,3,1,2,\text{-},4] & B_4 = [0,1,1,1,0] \\ P_5 = [0,2,3,1,4] & \bar{P}_5 = [0,3,1,2,4,\text{-}] & B_5 = [0,1,1,1,1] \end{array}
```

The first row and the first column are determined. Each row has n elements. We also use the data structure for an inverse array \bar{P} , which is essentially the inverse permutation of the rows. The j-th element of \bar{P}_i gives the position in P_i where the crossing with j occurs. The diagonal entries are irrelevant. The column indices in \bar{P} range from 0 to n; therefore we define the rows to have maximum length MAXN + 1.

 \langle Types and data structures $5\rangle + \equiv$

typedef int PSLA [MAXN + 1] [MAXN + 1];

1.5.1 Linked representation

10

For modifying and extending PSLAs, it is best to work with a linked representation.

Point (j, k) describes the crossing with line k along the line j. SUCC(j, k) and PRED(j, k) point to the next and previous crossing on line j. For (k, j) we get the corresponding information for the line k. In the example, we have SUCC(2,3) = 5 and accordingly PRED(2,5) = 3.

The infinite rays on line j are represented by the additional line 0: SUCC(j,0) is the first (leftmost) crossing on line j, and PRED(j,0) is the last crossing. The intersections on line 0 are cyclically ordered $1, \ldots, n$. Thus, $SUCC(0,i) \leftarrow i+1$ and SUCC(0,n)=1.

The program works with a single linked-list representation, which is stored in the global arrays *succ* and *pred*.

```
#define SUCC(i,j) succ[i][j] /* access macros */
#define PRED(i,j) pred[i][j]
#define LINK(j,k1,k2)

{ /* make crossing with k_1 and k_2 adjacent on line j */
SUCC(j,k1) \leftarrow k2;
PRED(j,k2) \leftarrow k1;
}

(Global variables 10) \equiv
int succ[\mathbf{MAXN} + 1][\mathbf{MAXN} + 1];
int pred[\mathbf{MAXN} + 1][\mathbf{MAXN} + 1];
See also chunks 16, 26, 31, 35, 44, 48*, 61*, and 64*
This code is used in chunk 3*.
```

1.6 Recursive Enumeration

We extend an x-monotone pseudoline arrangement of n-1 lines 1, ..., n-1, by threading an additional line n through it from the bottom face to the top face. The new line gets the largest slope of all lines.

Line 0 crosses the other lines in the order 1, 2, ..., n.

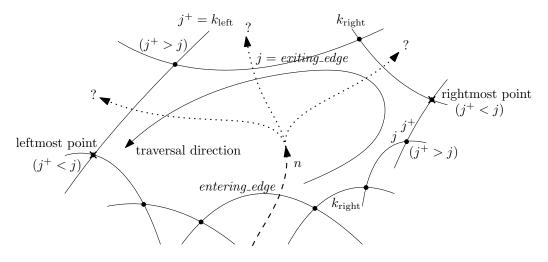

Figure 2: Threading line n through a face

```
12 ¶(Core subroutine for recursive generation 12) ≡ void recursive_generate_PSLA_start(int n); void recursive_generate_PSLA(int entering_edge, int k_{\text{right}}, int n) { /* The new line enters a face F from the bottom. The edge through which it crosses is part of line entering_edge, and its endpoint is the crossing with k_{\text{right}}. */
int j \leftarrow entering_edge;
int j^+ \leftarrow k_{\text{right}};
while (j^+ > j) { /* find right vertex of the current cell F */
int j^+_{\text{old}} \leftarrow j^+;
j^+ \leftarrow \text{SUCC}(j^+, j);
j \leftarrow j^+_{\text{old}};
```

```
/* the right vertex is the intersection of j and j^+ */
         if (j^+ \equiv 0) { /* F is unbounded */
                                 /* F is the top face. */
            if (j \equiv n-1) {
               LINK(n, entering\_edge, 0); /* complete the insertion of line n */
               (Update counters 15)
               \langle \text{ Indicate Progress } 14 \rangle;
               \langle Check for exclusion and set the flag is_excluded 20\rangle
               if (is_excluded) return;
               (Gather statistics about the AOT, collect output 50)
               (Further processing of the AOT 52)
               if (n < n_{-}max)
                 if (n \neq split\_level \lor countPSLA[n] \% parts \equiv part) {

This code is used in chunk 12.
      Handling the exclude-file
The array excluded_code [3... excluded_length] contains the decimal code of the next PSLA that should be ex-
cluded from the enumeration. During the enumeration, the decimal code of the currently visited tree node (as
stored in localCountPSLA) agrees with excluded_code up to position matched_length.
   It is assumed that the codes in the exclude-file are sorted in strictly increasing lexicographic order, and no
code is a prefix of another code.
\langle \text{Global variables } 10 \rangle + \equiv
  unsigned excluded\_code[MAXN + 3];
```

```
Code is a prefix of another code.
(Global variables 10) +≡
    unsigned excluded_code [MAXN +3];
    int excluded_length ← 0;
    int matched_length ← 0; /* These initial values will never lead to any match. */
    FILE *exclude_file;
    char exclude_file_line [100];
¶⟨Open the exclude-file and read first line 17⟩ ≡

```
\langle \text{ Determine the matched length } matched\_length \ \ 19 \rangle \equiv \\ matched\_length \leftarrow 2; \\ \textbf{while } (excluded\_code[matched\_length + 1] \equiv localCountPSLA[matched\_length + 1] \land matched\_length < \\ excluded\_length \land matched\_length < n) \\ matched\_length ++; \\ \text{This code is used in chunk 20.}
```

This code is used in chunk 12.

This code is used in chunk 3*.

1.8 Conversion between different representations

¶ Convert from linked list to array.

Input: PSLA with n lines 1..n, stored in succ. Output: PSLA-Array P of size $(n+1)\times(n-1)$ for pseudoline arrangement on n pseudolines.

¶ The inverse PSLA matrix $\bar{P} = I = invP$ gives the following information: $I_{jk} = p$ if the intersection between line j and line k is the p-th intersection on line j (p = 0, ..., n - 1). This is used to answer orientation queries about the pseudoline arrangement, and about the dual point set, see Section 1.9.

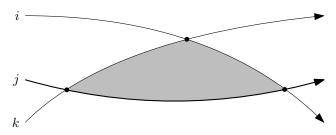

```
 \begin{array}{l} \text{(Subroutines 22)} += \\ \textbf{void } convert\_to\_inverse\_PS\_array(\textbf{PSLA} *invP, \textbf{int } n) \\ \\ \{ & \textbf{int } j \leftarrow 1; \\ \textbf{for\_int\_from\_to } (i,0,n) \text{ } \\ & \textbf{for\_int\_from\_to } (p,0,n-1) \text{ } \\ & (*invP)[i][j] \leftarrow p; \\ & j \leftarrow \texttt{SUCC}(i,j); \\ \\ \} \\ & j \leftarrow 0; \qquad /* \text{ j starts at } 0 \text{ except for the very first line. } */ \\ \\ \} \\ \end{array}
```

1.9 The Orientation Predicate

We compute the orientation predicate in constant time from the inverse permutation array I. It is a **boolean** predicate that returns true if the points i, j, k are in counterclockwise order. It works only when the three indices are distinct.

It is computed by comparing the intersections on line j.

If i < j < k, this predicate is *true* if the intersection of lines i and k lies above line j. When i, j, k are permuted, the predicate must change according to the sign of the permutation. For documentation purposes, we specify an expression $getOrientation_explicit$ that distinguishes all 3! possibilities in which the indices i, j, k can be ordered. getOrientation is a simpler, equivalent, expression.

```
#define getOrientation\_explicit(I, i, j, k)

(i < j \land j < k ? I[i][j] > I[i][k] : i < k \land k < j ? I[i][j] > I[i][k] : j < i \land i < k ? I[i][j] < I[i][k] : j < k \land k < i ? I[i][j] > I[i][k] : k < j \land j < i ? I[i][j] > I[i][k] : k < i \land i < j ? I[i][j] < I[i][k] : 0)
#define getOrientation(I, i, j, k) ((i < j) \oplus (j < k) \oplus (I[j][i] > I[j][k]))
```

¶ extreme points from the PSLA.

25

This is easy; we just scan the top face. We know that 0, 1, and n belong to the convex hull. 0 represents the line at ∞).

The input is taken from the global variable *succ*. (*pred* is not used.)

1.10 Unique identifiers, accession numbers, Dewey decimal notation

The recursive enumeration algorithm imposes an implicit tree structure on PSLAs: the parents of a PSLA with n lines is the unique PSLA on n-1 lines from which it is generated. We number the children of each node in the order in which they are generated, starting from 1. The sequence of labels on the path from the root to a node gives a unique identifier to each node in the tree. (This is, however, specific to details of the enumeration algorithm: in which order edges are considered for crossing in the insertion, the choice of lexicographic criterion.)

The purpose of this scheme is that it allows to identify a PSLA even if we parallelize the computation, and one thread of the program only visits certain branches of the tree.

```
6 \langle \text{Global variables } 10 \rangle + \equiv 
unsigned localCountPSLA[\mathbf{MAXN} + 3];
```

```

```

1.11.1 Fingerprints

```
 \begin{array}{ll} & \text{void } print\_pseudolines\_short(\mathbf{PSLA} *P, \mathbf{int} \ n) \\ \{ & printf("P"); \\ & \mathbf{for\_int\_from\_to} \ (i,0,n) \ \{ \\ & printf("!"); \\ & \mathbf{for\_int\_from\_to} \ (j,0,n-1) \ printf("\%c", \texttt{TO\_CHAR}((*P)[i][j])); \\ \} & printf("\n"); \\ \} \\ & \mathbf{void} \ print\_pseudolines\_compact(\mathbf{PSLA} *P, \mathbf{int} \ n) \\ \{ & /* \ line \ 0 \ is \ always \ 1234... */ \\ & \mathbf{for\_int\_from\_to} \ (i,1,n) \ \{ & /* \ line \ P_i \ starts \ with \ 0 \ and \ is \ a \ permutation \ that \ misses \ i... */ \\ & \mathbf{if} \ (i>1) \ printf("!"); \\ & \mathbf{for\_int\_from\_to} \ (j,1,n-2) \ printf("\%c", \texttt{TO\_CHAR}((*P)[i][j])); \\ \} \\ \} \\ \end{array}
```

A more compact fingerprint

```
Sufficient to know
```

```
B_i[j] = 1 if P_i[j] < i, see Felsner, Chapter 6.
```

binary arrays B_1, \ldots, B_n . The first column is fixed. The first row B_1 and the last row B_n is fixed, and they need not be coded. Also, since row B_i contains i-1 ones, we can omit the last entry per row, since it can be reconstructed from the remaining entries. Thus we encode the $(n-2) \times (n-2)$ array obtained removing the bordere from the original $n \times n$ array.

We code 6 bits into an ASCII symbol, using the small and capital letters, the digits, and the symbols + and

Since we use this encoding for the case when n is known, we need not worry about terminating the code. (Replace matrices would offer even more savings.)

```
#define FINGERPRINT_LENGTH 30 /* enough for 13 \times 13 bits plus terminating null */ \langle Global variables 10 \rangle += char fingerprint[FINGERPRINT_LENGTH];
```

```
32 \P{Subroutines 22} += char encode_bits(int acc) {
    if (acc < 26) return (char)(acc + (int) 'A');
    else if (acc < 52) return (char)(acc - 26 + (int) 'a');
    else if (acc < 62) return (char)(acc - 52 + (int) '0');
    else if (acc \equiv 62) return '+';
    else return '-';
```

```
void compute\_fingerprint(\mathbf{PSLA} *P, \mathbf{int} n)
   {
     int charpos \leftarrow 0;
     int bit\_num \leftarrow 0;
     int acc \leftarrow 0;

1.12 Abstract order types

1.12.1 Lexmin for PSLA Representation

In order to generate every AOT only once, we check whether the representation is smallest among all PSLAs that produce AOTs, that are *equivalent* by rotation and reflection.

Lexicographically smallest. We have to try all "boundary points" (?) as pivot points. The average number of extreme vertices is slightly less than 4. It does not pay off to shorten the loop considerably. (The average squared face size matters!)

To determine !!!! whether a PSLA is the lex-smallest among all PSLAs representing an AOT, we scan the PSLA matrix row-wise *from right to left*. In comparison with the more natural left-to-right order, this gives, experimentally, a quicker way to eliminate tentative PSLA than the left-to-right order.

```
\langle Global variables 10\rangle + \equiv
35
                                  int Sequence[MAXN +1][MAXN +1];
                                                    /* Sequence [r][p] gives the p-th crossing on the r-th hull edge. */
                                  int new\_label[\mathbf{MAXN} + 1][\mathbf{MAXN} + 1]; /* When the r-th hull edge is used in the role of line 0,
                                                          new\_label[r][j] gives index that is use for the (original) line j. */

             \langle Process candidate c, keep in list and advance new_candidates if equal; reset new_candidates if
                  better value than current_min 38
          numcandidates\_forward \leftarrow new\_candidates\_forward;
          numcandidates \leftarrow new\_candidates;
          (*P)[p][n-q] \leftarrow current\_min;
                                                 /* could enter a shortcut as soon as numcandidates \equiv 1 */
       }
     }
  }
```

 \P The list of candidates is scanned and simultaneously overwritten with new values.

38 \langle Process candidate c, keep in list and advance $new_candidates$ if equal; reset $new_candidates$ if better value than $current_min\ 38 \rangle \equiv$

```
int r \leftarrow candidate[c];
  int i \leftarrow Sequence[r][pos];
                                       /* We are proceeding on line i */
  int j \leftarrow current\_crossing[c];
  j \leftarrow reversed ? SUCC(i, j) : PRED(i, j);
  int a \leftarrow new\_label[r][j];
  if (reversed \land a \neq 0) a \leftarrow n + 1 - a;
  if (a < current\_min)
                                 /* new record: */
     new\_candidates \leftarrow new\_candidates\_forward \leftarrow 0;
     current\_min \leftarrow a;
  if (a \equiv current\_min) {
                                 /* candidate survives. */
     candidate[new\_candidates] \leftarrow r;
     current\_crossing[new\_candidates] \leftarrow j;
     new\_candidates ++;
         /* Otherwise the candidate is skipped. */
This code is used in chunk 37.
```

 \P The output parameters have only a meaning if the test returns $true.\ has_fixpoint$ is only set if the PSLA is mirror-symmetric.

We scan the entries of P row-wise from right to left. We maintain a list of solutions, which are still candidates to be lex-smallest. Initially we have $2 \times hullsize$ candidates, hullsize "forward" candidates and the same number of mirror-symmetric, reversed candidates.

Candidates $0..numcandidates_forward-1$ are forward candidates. The remaining candidates up to numcandidates-1 are reverse (mirror) candidates.

If information about mirror symmetry is not necessary, then the mirror candidates can be omitted.

1.13 Streamlined version

Fast screening of candidates

Let i and j be two consecutive edges on the upper envelope. The quantity Q(i,j) is defined as follows, see Figure 3a.

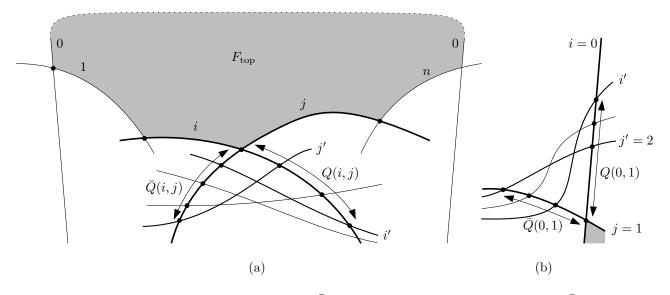

Figure 3: (a) An example with Q(i,j)=4 and $\bar{Q}(i,j)=5$; (b) an example with $Q(0,1)=\bar{Q}(0,1)=4$

Let i' = PRED(i, j). Walk on line i to the right (by SUCC) from the intersection between i and j until meeting the intersection with i'. Then Q(i, j) is the number of visited points on i, including the endpoints. This convention ensures that Q(i, j) is the value P_{1n} when line i is chosen to play the role of line 0, (and j will become line 1). In the walk along i, we may cross line 0 and wrap around to the left end.

The quantity $\bar{Q}(i,j)$ is defined with switched roles of i and j and with left and right exchanged, and it gives the value P_{1n} in the mirror situation (the *backward* direction) when line j is chosen to play the role of line 0: Let j' = SUCC(i,j). Walk on line j to the left (by PRED) until meeting line j'.

We apply this definition two all pairs (i, j) of consecutive edges on the upper envelope, starting with (0, 1) and ending with (n, 0). (The last pair is the only pair with i > j.)

```
The numbers Q(i,j) and \bar{Q}(i,j) are between 2 and n, and Q(i,j)=2 \iff \bar{Q}(i,j)=2.
```

For (i,j) = (0,1), the wedge between lines i and j appears actually at the bottom right of the wiring diagram, see Figure 3b. Here we have $Q(0,1) = PRED(1,0) = P_{1n}$, since this is the original situation where line 0 is where it should be. Similarly, for (i,j) = (n,0), we have to look at the bottom left corner.

Our primary criterion in comparing candidates is P_{1n} which is given by Q(i,j) and $\bar{Q}(i,j)$ for the pairs (i,j) of consecutive edges on the upper envelope. This has to be compared against. Q(0,1).

¶ Screen candidates by comparing the leading entry P_{1n} ,

Compute the leading entry P_{1n} for all candidates directly, without first computing the *label_arrays*. The *label_arrays* are computed afterwards (if at all), and only those that are still necessary. This saves about 20 % of the runtime for enumerating AOTs. If $P_{1n} = 2$ for line 0, the screening has no effect, but otherwise there is a high chance for finding a smaller value P_{1n} for some of the other candidates.

[Observation. The relative frequence of P_{1n} over all PSLAs is about 26% for 2 and n, about 11% for 3 and n-1 and decreases towards the middle values. The symmetry can be explained as follows. An xPSLA is essentially a projective oriented PSLA with a marked angle. Going to an adjacent angle and mirroring the PSLA exchanges a with n+2-a.

The following program treats each forward candidate i together with the corresponding mirror candidate j. it uses the condition $Q(i,j)=2\iff \bar{Q}(i,j)=2$ to shortcut the computation. (not sure if it brings any advantage.)

For example there are 18,410,581,880 PSLAs with n=10 lines. Of these, only 5,910,452,118 pass the screening test. Eventually, only 2,343,203,071 PSLA are really lex-min, and this is the number of AOTs that we really want.

```
\langle Subroutines 22\rangle + \equiv

```

 \P More effective screening at the previous level.

Rather than generating many PSLAs with n lines and eliminating them by screening, it is better not to generate them at all, or to generate only those that have a change of surviving the screening test.

To do this, we apply a test at the previous level.

When adding a new line n, the quantities Q(i,j) can change in a few ways.

- 1. We cut off some hull vertices. In particular, (n-1,0) will always disappear.
- 2. We generate two new hull vertices: (i, n) with $1 \le i \le n 1$, and (n, 0).
- 3. In the definition of Q(i,j), line n could take the role of i'. (or j' in the case of $\bar{Q}(i,j)$).
- 4. In the definition of Q(i,j), line n could intervene between the intersections with j and i' on line i, thus increasing Q(i,j) by 1. (or a similar situation for $\bar{Q}(i,j)$).

A very rudimentary pre-screening test has been implemented, namely for the comparison between Q(0,1) and $\bar{Q}(1,0)$:

If $\bar{Q}(0,1) < Q(1,0) - 1$ in the arrangement with n-1 lines, then there is no chance to augment this to a lex-min PSLA.

Proof: See Figure 3b. There are two cases. If line n does not intersect the segment between 1×0 and $1 \times PRED(1,0)$, then $Q(0,1) = P_{1n}$ is unchanged. $\bar{Q}(1,0)$ can increase by at most 1. Thus $\bar{Q}(1,0)$ will beat Q(1,0).

If line n intersects line 1 between 1×0 and $1 \times PRED(1,0)$, then n becomes the new $i' = PRED(1,0) = Q(0,1) = P_{1n}$, and thus P_{1n} has the maximum possible value, n, and is certainly larger than before. $\bar{Q}(1,0)$ can still increase by at most 1. Thus $\bar{Q}(1,0)$ will beat Q(1,0).

For example, with n=9 lines there are 112,018,190 PSLAs, and they generate as children 18,410,581,880 PSLAs with n=10 lines, as mentioned above. The screening test at level n=9 eliminates 22,023,041 out of the 112,018,190 PSLAs (19.66%) because they are not able to produce a lex-min AOT in the next generation. The remaining 89,995,149 PSLAs produce 15,409,623,219 offspring PSLAs with n=10 lines. as opposed to 18,410,581,880 without this pruning procedure. These remaining PSLAs are subject to the screening as before.

```
43 ¶ (Screen one level below level n\_max 43 \rangle \equiv
int P\_1\_n \leftarrow \text{PRED}(1,0); /* insertion of last line n can only make this larger. */
if (P\_1\_n > 3) {
int a \leftarrow 2;
int i2 \leftarrow P\_1\_n; /* \equiv i' */
while (i2 \neq 2) { /* compute a by running along j \equiv 1 */
i2 \leftarrow \text{PRED}(1,i2);
a++;
} /* Now P\_1\_n\_reverse \equiv a but insertion of line n could increase this by 1. */
if (a+1 < P\_1\_n) hopeful \leftarrow false;
}
if (hopeful) cpass++; else csaved++;
This code is used in chunk 12.
```

1.14 Statistics

Characteristics:

- number h of hull points.
- period p of rotational symmetry on the hull. (The order of the rotation group is h/p.)
- mirror symmetry, with or without fixpoint on the hull (3 possibilities).

PSLAcount gives OAOT of point sets with a marked point on the convex hull. http://oeis.org/A006245 (see below) is the same sequence with n shifted by 0.

1.15 Data Structures for Abstract Order Types

¶ Small Λ -matrices.

In this program, entries Λ_{ijk} of the large matrix are only ever accessed for i < j < k. For more general access, we provide the macro get_entry_large . It would be possible to save space by a more elaborate indexing function into a one-dimensional array.

natural labeling around the pivot point, which is assumed to lie on the convex hull.

```
55 #define entry\_small(A, i, j) (A)[i][j]
```

¶ More type definitions.

```
56 \(\text{Types and data structures 5}\) +\(\perp \)
typedef \(\text{uint_fast8_t}XXsmall_matrix_entry;\) /* suffices up to \(n = 255 + 1 \ */\)
typedef \(\text{int_fast8_t}XXsmall_int;\) /* suffices for \(n \ */\)
typedef \(\text{boolean large_matrix_entry};\)
typedef \(\text{unsigned small_matrix_entry};\)
```

```
typedef int small_int; /* simpler and maybe even faster? */
typedef small_matrix_entry small_matrix [MAXN +1][MAXN +1];
typedef large_matrix_entry large_matrix [MAXN +1][MAXN +1][MAXN +1];
```

¶ Generating the large Λ -matrix. Only for testing purposes. Assumes natural ordering. Assumes general position. Works by plucking points from the convex hull one by one.

```

1.18 Extension

Compute crossing-number for each AOT.

By https://oeis.org/A076523, a set with n=12 points (the maximum that the program is set up to deal with), has at most 18 halving-lines. According to S. Bereg and M. Haghpanah, New algorithms and bounds for halving pseudolines, Discrete Applied Mathematics 319 (2022) 194–206, https://doi.org/10.1016/j.dam. 2021.05.029, Table 1 on p. 196, the number of halving lines-with for odd numbers n of points are nearly 70% higher than for the adjacent even values. With a bound of 50 we should be on the safe side. n=11 point has at most 24 halving-lines

```
#define MAX_HALVING_LINES 24
#define MAX_CROSSINGS (MAXN +1) *MAXN *(MAXN -1)*(MAXN -2) / 24
/* crossing-number goes up to \binom{n}{4} for n points */
```

 \P^* How to check for a crossing.

This algorithm is like the program for drawing the wiring diagram, except that it does not draw anything consecutive tracks p and p + 1. */

Use the formular from Convex quadrilaterals and k-sets, DOI:10.1090/conm/342/06138

The program computes the number of crossings $num_crossings_on_level[p]$ at each level p except for the crossings with line 0. (From this information, there is actually an easy formula to compute the crossing number of the complete graph K_n when it is drawn on this point set.)

```
\#define CHECK_CROSSING(p)
               int i \leftarrow line\_at[p];
               int j \leftarrow line\_at[p+1];
               if (i < j \land next\_crossing[i] > i \land next\_crossing[j] < j \land next\_crossing[j] \neq 0)
                     /* Line i wants to cross down and line j wants to cross up. */
                     /* (In this case, we must actually have next\_crossing[i] \equiv j and next\_crossing[j] \equiv i.) */
                  crossings[num\_crossings \leftrightarrow] \leftarrow p;
                     /* The value p indicates a crossing between tracks p and p + 1. */
            }
          }
\langle \text{Subroutines } 22 \rangle + \equiv

  return crossing_formula/4;
}
```

1.19 Reading from the Order-Type Database

```
work Only the 16-bit formats.

64 ⟨Global variables 10⟩ +≡

struct { /* 16-bit unsigned coordinates: */

uint16_tx, y;
} points[MAXN +1];

struct { /* 8-bit unsigned coordinates: */

uint8_tx, y;
} pointsmall[MAXN +1];
```

Orientation test for points

The return value of orientation_test is positive for counterclockwise orientation of the points i, j, k.

```
65 \langle \text{Subroutines } 22 \rangle +\equiv \\ \text{large\_int } orientation\_test(\text{int } i, \text{int } j, \text{int } k) \\ \{ \\ \text{large\_int } a \leftarrow points[j].x - (\text{large\_int}) \ points[i].x; \\ \text{large\_int } b \leftarrow points[j].y - (\text{large\_int}) \ points[i].y; \\ \text{large\_int } c \leftarrow points[k].x - (\text{large\_int}) \ points[i].x; \\ \text{large\_int } d \leftarrow points[k].y - (\text{large\_int}) \ points[i].y; \\ \text{return } a*d-b*c; \\ \}
```

 \P^* Intermediate results can be almost 2^{32} in absolute value, and they have signs. The final value is the signed area of the parallelogram spanned by 3 points. Thus it can also be almost 2^{32} in absolute value. 32 bits are not enough to be safe. We use 64 bits.

```
\langle \text{Types and data structures } 5 \rangle + \equiv 
typedef int_least64_t large_int; /* for intermediate calculations */
```

Turn point set with coordinates into PSLA

We insert the lines one by one into the arrangement. This is simular to the insertion of line n in the recursive enumeration procedure. The difference is that we don't try all possibilities for the edge through which line n exits, but we choose the correct edge the by orientation test. By the zone theorem, the insertion of line n takes O(n) time.

We have n points. The first point (point 0) is on the convex hull and the other points are sorted around this point. We get a PSLA with n-1 pseudolines.

```
\langle Subroutines 22\rangle + \equiv
  void insert\_line(int n);
  void PSLA\_from\_points(\mathbf{int} \ n)
     LINK(1, 0, 2);

List of Refinements

```
\langle Check for exclusion and set the flag is_excluded 20\rangle Used in chunk 12.
(Compare orientation tests 53) Used in chunk 52.
Core subroutine for recursive generation 12 \ Used in chunk 3^*.
Determine the matched length matched_length 19 \rangle Used in chunk 20.
Determine the result parameters, depending on the remaining candidates. 47 Used in chunk 45.
Further processing of the AOT 52 \ Used in chunk 12.
Gather statistics about the AOT, collect output 50 \ Used in chunk 12.
Get the next excluded decimal code from the exclude-file 18 \rangle Used in chunks 17 and 20.
Global variables 10 16 26 31 35 44 48 61 64 \ Used in chunk 3*.
Include standard libaries 6 68 \ Used in chunk 3*.
Indicate Progress 14 \ Used in chunk 12.
Initialize statistics and open reporting file 49 \ Used in chunk 3*.
Open the exclude-file and read first line 17 \ Used in chunk 60.
Parse the command line 60 Vsed in chunk 3^*.
Print PSLA-fingerprint 33 \ Used in chunk 52.
\langle Process candidate c, keep in list and advance new_candidates if equal; reset new_candidates if better value
    than current\_min 38 Used in chunk 37.
\langle Process candidate c, keep in list and advance new_candidates if successful; return false if better value than
    target_value is found 46 \ Used in chunk 45.
\langle \text{Read all point sets of size } n_{-}max + 1 \text{ from the database and process them } 70 \rangle Used in chunk 3*.
Report statistics 51 \ Used in chunk 3*.
Screen one level below level n_{-}max = 43 Used in chunk 12.
Start the generation 13 \rightarrow Used in chunk 3*.
Subroutines 22 23 25 27 29 30 32 36 37 41 45 57 59 63 65 67 69 71 \ Used in chunk 3*.
\langle \text{ Types and data structures 5 9 56 66} \rangle Used in chunk 3*.
(Update counters 15) Used in chunk 12.
